However legalistic and humane the intention and theory might have been, it was often the case that no sooner did an Inquisition begin in a locality than draconian justice took over. To begin with, the basic proceedings of the Inquisition were flawed. Viewed more as a confessional than a legal proceeding, it usually began by trying to persuade a suspect to confess his or her error. To confess and seek absolution was to receive mercy and forgiveness, although some penalty or penance was also applied. If a person failed to confess, after failed attempts at counsel and persuasion, the accused would often be subjected to a secret trial during which no legal counsel was permitted and no formal rules of evidence were at work, and a confession could be obtained by torture. After conviction, the heretics deemed the most obstinate and dangerous were often delivered to the secular arm to be burned at the stake and their goods confiscated. Therefore, the outcome of an Inquisition depended greatly on the motives, beliefs, humanity, and integrity of the inquisitors. In addition, seldom would an Inquisition be carried out as formally and as humanely as the Church intended. Local lay and ecclesiastical leaders had interests at stake (and often personal vendettas to settle), and moreover, local religious fanatics often played active roles in convicting the accused through the pressure of public opinion and perjured testimony.

Beginning in the fourteenth century, the Latin West went through a volatile and profound social and political transformation due to many factors, including climate change, the Black Death, the Hundred Years' War between the English and French monarchs, the Great Schism within the Catholic Church itself, the increase of commercial activities domestically and overseas, and the restructuring of rural society and royal governance.

In the midst of this maelstrom, movements of popular piety gained momentum in the worship of sacred images whereby some untutored laypeople lapsed into various forms of idolatry. The Church certainly was worried lest pious veneration of holy objects and symbols degenerate into image worship, but the Catholic elites, including some prominent popes of the later medieval period, sincerely embraced the forms and some of the ideas of Greek humanism and encouraged experiments in new artistic expressions of biblical prophecy and the Catholic faith. Their efforts encouraged the boom in the early Renaissance's humanistic arts and literature, but they also added to the sum total of captivating, often starkly realistic statues and paintings that some of the faithful were using not as aids to prayer and devotion but as objects of devotion.

At the same time, movements of popular piety became increasingly concerned with addressing social injustices and challenging the mischief, both real and perceived, caused by church institutions and unworthy clerics. The Lollards inspired by John Wycliffe (ca. 1330–1384) in England, the Hussites who were attracted to the teaching of John Hus (1370–1415) in Bohemia, and various other sects hostile to papal authority in continental Europe shook the very foundations of Roman Catholic unity. The Church increased and intensified trials for and denunciations of heresy, witchcraft, magic, and superstition. Regardless, more and more people, particularly north of the Alps, became willing to affiliate with the novel ideas and simple practices of heresy to protest clerical abuses and the perceived errors of Catholic orthodoxy and to demonstrate their overall discontentment with the establishment. And heretical theologians, who took the lead in this attack, fought the Roman Church on numerous fronts, attacking its moral

decay; contesting its interpretations of Scripture and its traditions, such as monasticism; rejecting its priest-centered liturgy and sacraments; and denying its claimed legitimacy as the sole avenue to salvation. Such attacks were sometimes supported by regional lords and even occasionally earned some degree of sympathy from secular kings.

In the sixteenth century, heresy eventually merged into the Reformation, which in turn religiously decentralized the old Catholic world. At the same time, various Christian pietistic movements, both within the bounds of Roman Catholic orthodoxy and outside of it, continued to emerge, grow, and fight, in an ever more diversified Christian culture, for their freedom of worship and belief.

Orthodoxy and Heresy in the Latin West

The half millennium between 1000 and 1500 was a period of intense intellectual and theological activity in the Latin West during which the institutional Church became more rigid and centralized, while popular religious movements, many of them anticlerical and antiauthoritarian, sprang up and spread across Europe. The papacy emerged from a period of impotence and subservience to secular rulers and attempted to establish itself as the ultimate spiritual authority in Christendom and a political power. This authority and power often ended up being exercised

► THE BEGUINES—FEMININE MYSTICISM IN WESTERN EUROPE

Arising in the twelfth-century Low Countries, the Beguine movement began with the desire of unmarried or widowed lay women, many of whom worked in the textile industries of northern Europe, to live a communal, spiritual life without taking formal, life-long vows that joined them to an organized religious order of the Roman Catholic Church. Their name derives from an early spiritual advisor, Lambert le Bègue, a priest of Liège. Beguines had the freedom to form whatever type of community they deemed most appropriate, but all vowed chastity while living in the community, though they were free to leave at any time. They did not take the traditional monastic vows of obedience and poverty, but pledged to work with their hands, and many communities took it upon themselves to minister to the needy. Most communities resided in cities or towns, but not all.

One common feature of the Beguines was their predilection toward mysticism. Many of their devotions centered on either the image of the primeval monastic desert of the early Christian centuries or the image of the mystical marriage of soul and Christ, which relied heavily on a spiritualized erotic metaphor. The movement was persecuted as a heretical sect beginning in the late thirteenth century, and troubles plagued the groups for years thereafter. Eventually, most Beguines were incorporated into the Church's regular orders.

against those who sought to pursue forms of belief or spiritual practices outside of ecclesiastical norms. Another consequence of this growth of papal claims to supremacy over the Church was a widening rift between the Churches of Rome and Constantinople.

Within the Church, the eleventh and early twelfth centuries were dominated by attempts

at moral reform that had long-term political consequences. The reform movement is generally called the Gregorian Reform after Pope Gregory VII (r. 1073–1085), although some of the policies he implemented were proposed by his predecessors. The reformers sought to end simony (the practice of buying and selling ecclesiastical offices) and lay investiture (the appointment of church officials by secular rulers) and to impose celibacy on all clergy. The ensuing controversy resulted in a greater degree of independence for the Church from secular control and the increased use of canon (church) law and church councils to enforce ecclesiastical policy from the papacy down to the lowest levels.

One of the most important tools of papal governance to emerge was the church council. During the Gregorian reform papal legates and even popes traveled across Europe, summoning local councils at which regional bishops were expected to implement the reformist agenda. In addition to these local councils, nine ecumenical councils (councils supposedly representing the Church as a whole) were called by the papacy and held in the West between 1123 and 1445. The First Lateran Council met in 1123 to confirm the agreement reached between Pope Callixtus (r. 1119–1124) and Emperor Henry V (r. 1106–1125) that ended the Investiture Controversy. It also issued 22 canons, or regulations, most of which expressed the aims of the Gregorian reformers. The Second Lateran Council (1139) had as its immediate purpose the goal of repairing problems caused by a schism between the supporters of Pope Innocent II (r. 1130–1143) and the followers of Antipope Anacletus II (d. 1138). The Third Lateran Council (1179) also met in the aftermath of a schism, and among its canons were provisions to ensure smoother papal elections. The Waldensian and Cathar heresies were also a topic of discussion, as was the behavior of the ordained religious. The Fourth Lateran Council (1215), widely considered the most important ecumenical council of the High Middle Ages, covered a wide range of topics. They included efforts to combat heresy, plans for the Fifth Crusade, liturgical and doctrinal matters (such as mandating that the laity confess and take communion at least once a year and approval of the doctrine of transubstantiation, the belief that

bread and wine are transformed by a priest into Christ's body and blood), clerical independence and discipline, and the primacy of the papacy in religious matters.

The First Council of Lyons (1245) also made provisions for future crusading activity and ordered the excommunication and deposition of Emperor Frederick II (although the latter was never carried out). The Second Council of Lyons (1274) was called specifically to address the schism between the Greek and Latin churches, and while some progress was made during the council, it proved fleeting. The Council of Vienne (1311-1312), summoned partly on the insistence of King Philip IV of France, disbanded the Knights Templar. The Council of Constance (1414-1418) met in an attempt to end the Great Schism, which it did by deposing two competing popes, accepting the resignation of the third, and electing Pope Martin V (r. 1417-1431). Finally, the Council of Basel/Ferrara/Florence (1431-1445), while marked by conflict between the papacy and the council over who had greater authority, and despite moving its venue twice and eventually splitting into two schismatic councils, still managed to come close to mending the rift with the Greek Church. It also discussed the Hussite heresy and ecclesiastical reforms.

Some of the ideas put forward by the ecclesiastical reform movements as ideals of the more perfect religious life, such as celibacy and voluntary poverty, proved appealing to laypeople. In addition, the gap between the ideals of the reformers and reality, the recurring schisms in the Church, and the conflicts between secular and ecclesiastical powers led to disillusionment among lay Christians as well as provided circumstances in which alternative spiritualities could be pursued. Not all attempts to find different and theoretically holier forms of Christian living ended in heresy and persecution, but it is a fact that the period between 1000 and 1500 saw ever-increasing attempts by the Church to enforce its version of orthodoxy, through violence if necessary. The different varieties of heterodoxy and heresy often influenced and interacted with each other and can be broadly divided into three categories.

First were those groups that sought an ascetic life without taking traditional monastic vows. One of the earliest groups of this sort was the Walden-

sians, who were named after their founder, a burgher of Lyons known as Valdes or Waldo (d. ca. 1218). Waldo and his followers took vows of poverty and took up the life of wandering preachers. This brought them into conflict with the Church, and after their condemnation as heretics by the Third Lateran Council, the Waldensians began to preach rejection of the entire ecclesiastical hierarchy. About the same time that Waldo was preaching in France, namely the late twelfth century, groups of laymen and laywomen began to voluntarily undertake a quasi-monastic lifestyle in the Low Countries. Known as Beghards (men) and Beguines (women), these groups received a mixed reception. They attracted a degree of official suspicion (especially those members who engaged in more mystical practices), and they also enjoyed the support of some high-ranking and influential churchmen. Consequently, periods of papal approval alternated with periods of persecution. The Beguines and Beghards were occasionally associated with the Brethren of the Free Spirit, a nebulous group that apparently believed that God is in all things and that the mystical union of the individual soul with the Holy Spirit obviated the need for organized religion and its practices.

The second major thread in later medieval heresy was a dualistic faith known as Catharism (or Albigensianism) but often called Manicheism in medieval sources, although there is no clear connection between the Manichees of Late Antiquity and the medieval Cathars. Cathar dualism held that there are two gods: the evil, worldly, fleshy God of the Old Testament and the good, spiritual God of the New. Such beliefs, possibly with ties to early Gnostic Christianity, emerged in the Balkans in the tenth century, and Bogomilism (as the Eastern form of Christian dualism is called) spread to the Latin West along trade routes by the early twelfth century. It took root most thoroughly in Languedoc (southern France), where the Cathar Church became a viable alternative to the Roman Church. The Roman Church responded by condemning Cathar beliefs at a series of councils and in numerous papal letters, by instituting the Inquisition as a method of dealing with heresy, by approving new orders of preachers (the Dominicans and Franciscans), and in the end by calling for an internal crusade

(the Albigensian Crusade, 1209–1229). As a result, Catharism effectively disappeared from western Europe by the end of the fourteenth century.

The third major category included those groups that began as attempts to reform the Church but eventually, due to frustration with the ecclesiastical authorities or internal theological developments, split with orthodox Christianity entirely. In fourteenth-century England the followers of John Wyclif (1320–1384), known as the Lollards, called for the translation of the Bible into English, minimizing the role and authority of the priesthood, and adoption of a life of poverty and piety. Although heavily persecuted for centuries, some elements of Lollardy proved influential in the English Reformation. In Bohemia, the Hussites (followers of Jan Hus, ca. 1359–1415) proved troublesome to the established Church. Although the Hussite movement began mainly with demands for greater lay participation in the liturgy and removal of the clergy from the political sphere, it eventually developed into a national Church that was able to maintain itself as a religious, social, and military force, despite several crusades launched against its Bohemian devotees, until well after the medieval period. Both the Lollards and the Hussites influenced the Protestant Reformation of the sixteenth century, by which point the papacy was no longer able to present itself as the arbiter of orthodoxy for all of western Europe.

Conversions in Iberia

The Iberian Peninsula experienced two significant conversion movements in the European Middle Ages: from Christianity to Islam after the Muslim conquest in the eighth century, and from Islam and Judaism to Christianity in the course of the long reconquest of the eleventh through fifteenth centuries. Neither Muslim conquest nor Christian reconquest had as an object the conversion or expulsion of infidels; rather, they aimed at the displacement of the vanquished ruling classes and the redirection of tax revenues to the conquerors' fisc. That said, the success of the victors' societies provoked conquered peoples to adopt the cultural and religious practices of the new regimes to the measure that these were seen to fill needs that their own cultures could not provide. Under Christian rule, official coercion, popular violence, and proselytizing all failed ultimately to convert or integrate Jews and Muslims.

Scholarly opinion varies regarding the rate of conversion of Christians to Islam under Muslim rule, but the broad consensus is that the overwhelming bulk of the native population had converted by the late ninth century. Christians who adopted the cultural and linguistic manifestations of Islam but who retained their faith (known as *Mozarabs*) remained a significant minority into the twelfth century despite emigration to Christian lands. The descendants of converts (Arabic *muwallads*) often adopted the genealogy of Islamic patrons and were thus profoundly integrated into Andalusian society, although rebellions in the ninth century demonstrated that they maintained a distinct identity until that time. Jewish conversion to Islam was limited, but cultural assimilation was dramatic.

Under Christian rule before 1492, native Jews and Muslims (*Mudejars*) tended to be involved in

royal, ecclesiastical, and local economies (the former as financiers, the latter as producers and laborers) to such a degree that it was rarely in the interests of clerical or secular institutions to actively promote conversion. Nevertheless, the missionary ideal was publicly promoted, although subtle legal obstacles were often presented to would-be converts, who for their part found that adopting the Christian religion was no guarantee of social acceptance. In the thirteenth century, missionary work was undertaken by the Dominicans and Franciscans (including the lay brother Ramon Llull), who obliged non-Christians to attend sermons, studied the Hebrew and Arabic scriptures, lobbied against Muslim and Jewish participation in Christian society, wrote polemics, and engaged in public debates. None of these techniques yielded much success, except among the Muslim slave population, whose members saw conversion as a step toward manumission.

In the fourteenth century religious and social boundaries became more rigid as increasingly elaborate codes of dress and conduct were prescribed for minority members. Pressure on Jews increased with Christian competition in the economic spheres that they had previously dominated, and as clerics, frustrated by their failure to rationally convert Jews, characterized them as obstinate. Finally, these pressures increased as the population at large came to perceive marginal groups (including lepers and Muslims) as responsible for its misfortunes. Occasional outbreaks of violence, particularly during Eastertime, culminated in widespread pogroms in 1391. In the aftermath of these events many Jews converted out of either fear or opportunism, some secretly maintaining their beliefs as crypto-Jews (*Marranos*). Converts, however, remained marginalized by a society that distinguished between “old” and “new” Christians. In 1492, the Spanish kingdoms adopted policies that called for conversion or execution (with the option of exile in Castilian and Aragonese lands). Many Jews fled abroad, particularly to Muslim lands and the Netherlands; those who remained became a favorite target of the Inquisition.

Officially marginalized, Muslims occasionally rose in local revolts, which were sometimes responded to with mass deportations. Perceived, however, as less of a threat than the Jews, Mude-

➤ AFTER 1492—AN EPILOGUE

The sixteenth century was characterized by persecution, expulsion, and forced conversion in Portugal (1497), Castile (1502), Navarre (1515), and Aragon and Valencia (1526). Later in the century, the Inquisition and the prohibition of traditional culture prompted further revolts among the converts (*Moriscos*), while increasing reactionaryism in the Spanish Church and society led to the promulgation of decrees of expulsion from 1609. Over the following decade the Moriscos were exiled and sought refuge in North Africa and Ottoman territories.

—Alfred J. Andrea

jars’ resistance to conversion did not tend to elicit the violent reaction that the Jewish presence did until the late fifteenth century. Following the fall of Granada in 1492, pressure increased, thanks in part to the machinations of Archbishop Cisneros of Toledo and the military threat posed by the Turks.

Mozarabs

The Christian minority of Muslim-dominated Iberia that adopted the language and outward manifestations of Arabo-Islamic culture came to

➤ SISNANDO DAVÍDEZ

Sisnando Davídez, a Portuguese Mozarab, is emblematic of the changes that took place in the status and fortunes of Mozarab Christians with the advent of the Christian Reconquista in the mid-eleventh century. Having served as an official of the Muslim ruler of Seville, he became the first governor of Coimbra for Ferdinand I of Castile and León (1064) and of Toledo for his son Alfonso VI (1085), also serving as envoy to the courts of Zaragoza and Granada. In a famous speech to the Taifa king Abd Allah ibn Bulughghin, he enunciated Alfonso's program of Christian reconquest.

—Alfred J. Andrea

be referred to as Mozarabs (from the Arabic word *mustarib*, “would-be Arab”) in the later European Middle Ages.

In the centuries following the Islamic conquest of Iberia (711–715), the overwhelming majority of the native population converted to Islam, leaving a small but cohesive Christian minority, strongest in Toledo (the Visigothic metropolitanate) and Córdoba (the Muslim capital). Offered security in exchange for submission by the Islamic pact of *dhimma* (the “pact of protection” granted by Islam to non-Muslims), Christians were free to live and worship according to their traditions provided they did not affront Islam or challenge its authority. An episcopal structure survived at least into the ninth century, but family-dominated monasteries seem to have comprised the nuclei of piety.

Social pressures resulting from conversion to Islam and the encroachment of Arabic culture, and which precipitated the incidents of the mid-ninth-century “voluntary martyrs” of Córdoba, are reflected in the writings of St. Eulogius (d. 859), archbishop of Toledo and himself one of the last of these martyrs, and his contemporary Paul Alvar. The martyrs can be divided into two types. Technical apostates, that is, Muslim men's children who had been raised under the influence of a Christian mother or relatives, were put to death if they persisted in the Christian faith. Deliberate martyrs, by contrast, were Christians who provoked their own deaths by pub-

licly insulting the Islamic faith and subsequently refusing the various offers made by the Muslim authorities to secure pardon. Yet many Christians occupied important posts in the Muslim administration through the period of the caliphate (to ca. 1035); the tenth-century courtier, scientist, and diplomat Bishop Reccemund (Arabic Rab ibn Zayd) is an example. Some also chose to emigrate, settling in the frontier zone of the river Duero, where examples of their churches survive to this day.

With the fragmentation of the caliphate and the rise of the independent Taifa (factional) kingdoms in the eleventh century, the politico-military initiative passed to the Christian principalities of the Iberian Peninsula, provoking profound changes in the situation of the Mozarabs. With the arrival of the Almoravids and their domination of the Taifa kingdoms, the position of Mozarabs under Muslim domination deteriorated. Allegations that they had abetted the famous raid of Alfonso I of Aragon into the south of Spain in 1132 and thus abrogated their pact of protection led to a mass deportation to North Africa, where they and their descendants remained until the advent of the Almohads in the late twelfth century.

By the late eleventh century the Mozarabs clearly comprised a distinct ethnic group, a fact recognized in the privileges and promulgations of the Aragonese and Castilian kings. Despite their contacts with Christendom abroad, they had remained isolated from Latin innovations and maintained, for instance, their own “Visigothic” liturgy. This soon became a target for agents of the Roman Church, notably the Cistercians and Pope Gregory VII (r. 1073–1085), who provoked Alfonso VI to ban the rite following a rigged trial by ordeal to which it was subjected in 1077. Increasingly marginalized in Toledo itself, some Mozarabs emigrated to the principality of Valencia or to Aragonese lands, where they joined local Mozarabs and refugees whom Alfonso I had led back from his incursion into Almoravid territory.

Thanks to their facility with the Arabic language, learned Mozarabs played an important role in the transmission of classical and Arabic learning to the West, notably through the translation activity that took place in Toledo. But apart from

there, within a century or so Mozarabs seem to have been all but completely assimilated by the culture of the Latin Christian settlers who arrived with the Christian conquests. In 1500 the Mozarabic rite was rehabilitated, undoubtedly because it could no longer be construed in any way as a threat to the Roman Church.

Western European Visions of World Conversion

The eleventh through the fifteenth centuries were an era of broadening horizons for the Christian inhabitants of Western Europe, whose activities outside their borders included political expansion, crusading, pilgrimages, missionary work, and long-distance trade. At the same time, this growing involvement in the wider world was accompanied by an imagined expansion of what Christian Europeans envisioned as “Christendom” (*Christianitas*). Contemporaries defined Christendom as the community of right-believing and right-practicing Christians who were assembled under the authority and spiritual guidance of the Roman papacy. In reality, Christendom was confined to the regions of the Western, or Latin, Church. In theory, however, Christendom was without limits, able to encompass both the Western and Eastern Churches along with numerous peoples who had yet to hear the word of Christ. Reacting to their growing reach in the world, the Christians of Western Europe began to predict that believers and nonbelievers everywhere would be gathered together under the authority of the Roman Church before the consummation of history, namely the Last Judgment as prophesied in the Book of Revelation. This vision of a global conversion before the End of Time persisted into the early modern era of Europe’s overseas

expansion, continuing to shape how Christian Europeans saw their place in both the progression of history and the world.

From their origins, Christian ideas about the destiny of their Church and the meaning of history were universal in scope. According to the Gospels, Christ himself predicted that the end of history was near and would be accompanied by horrible apocalyptic tribulations. He also declared that his message of salvation would be offered to all the peoples of the world before the consummation of time (Matthew 24:14) and commanded his disciples to baptize among “all the nations” in the name of the Father, Son, and Holy Spirit (Matthew 28:19), thereby forming “one flock” of believers under “one shepherd” (John 10:16). Another tradition maintained that after the “fullness” of the Gentiles (i.e., non-Jewish peoples) had entered into the Church, a remnant of Israel (i.e., unconverted Jews) would also turn to the Christian faith (Romans 11:25). Over the ensuing centuries as the expectation of an imminent apocalypse waned among mainstream Christian communities, there was a growing realization that the universal spread of the Gospels, begun by the apostles, was an ongoing and as yet unfinished process.

During the eleventh through the fifteenth centuries, historical circumstances in Western Europe infused apocalyptic thought with a new vitality, reshaping ideas about the end of history and the universal spread of the Christian faith to the ends of the world. The growing power and authority of the Roman papacy during this period brought with it a sense that the bishops of Rome and their followers would oversee the creation of a global flock before the end of history. Two factors in particular contributed to this development. First, starting around the middle of the eleventh century, the so-called reform movement in the Roman Church brought about a far-reaching revolution in notions of papal authority over the universal body of the faithful. Although the ideology of the reform papacy was not explicitly set in apocalyptic terms, papal efforts to reshape the medieval world order were implicitly eschatological, anticipating the realization of God’s plan for his Church. Second, at the close of the eleventh century, the capture of Jerusalem from its Muslim rulers by the First Crusade on July 15,

► CHRISTOPHER COLUMBUS AND THE BOOK OF PROPHECIES

During 1501–1502, between his third and fourth voyages to the “New World,” Christopher Columbus and an assistant, a Carthusian monk from Italy named Gaspar Gorricio, compiled a collection of biblical authorities, prophecies, and other sources that seemed to predict both the Christian recovery of the holy places in Jerusalem and the conversion of the world’s peoples to Christianity. This collection, which became known as the *Book of Prophecies*, suggested that Columbus’s own voyages of exploration were part of a divine plan for the course of history, one that would see the spread of the Catholic Church throughout the globe before the approaching End of Time under the authority of his patrons, King Fernando II (r. 1479–1516) of Aragon and Queen Isabel (r. 1474–1506) of Castile.

It is clear from the *Book of Prophecies* along with his own correspondence and a number of works annotated in his own hand (including Marco Polo’s *Il milione*) that Columbus had read widely before and during his previous voyages in the fields of both geography and history, including materials that speculated about the course of future events. In his own writings, he drew upon a wide range of sources, including the well-known seventh-century prophecy of Pseudo-Methodius and texts that were attributed to the famous twelfth-century apocalyptic thinker Joachim of Fiore. In addition to seeking gold and trade routes, Columbus believed that he had a duty to spread Christendom throughout the entire globe, thereby helping to realize the “one flock” under “one shepherd” that had been promised by Christ to his disciples (John 10:16). Columbus persisted in these beliefs until the end of his life. During his fourth voyage, for example, writing to Fernando and Isabel, Columbus again predicted that the holy city of Jerusalem would be rebuilt by Christian hands and that the Christian faith would be spread to all the peoples of the world. In this sense, the voyages of Columbus, who is often portrayed as a modern thinker who dared to reject the received knowledge of the medieval past by journeying into the unknown, represented yet another stage in a long-standing Christian dream of world conversion.

—Brett Edward Whalen

1099, contributed to an unprecedented sense among the followers of the Roman Church that they were carrying out God’s will on a historical stage in a manner that had not been seen since the days of biblical Israel.

The twelfth and thirteenth centuries would prove to be an even more creative period in Christian European theories about the progression of history and the future of their Church due in large part to the apocalyptic thought of the highly influential mystic, biblical commentator, and monastic reformer Joachim of Fiore (1140–1202). Joachim envisioned a future union of the Latin and Greek Churches followed by the conversion of the Jews and the spread of Christianity to pagan peoples by a new spiritual order of monks. At points, he indicated that perhaps even Muslims would convert to the Christian faith. In 1204 not long after Joachim died, the capture of Constantinople by the Fourth Crusade seemed to promise to some in the Western Church, including Pope Innocent III (r. 1198–1216), that the reunion of Latins and Greeks was at hand, presaging the conversion of pagan peoples and the recovery of the Holy Land for Christendom before the end of time. Over the subsequent decades, the development of the Mongol empire connected Christian Europeans to a larger world than they had previously thought possible, suggesting that an alliance of converted Mongols and Christians might defeat Islam once and for all. In this environment, prophecies and apocalyptic schemes about the union of all Christian churches, the conversion of non-Christian peoples, and the spread of Christianity to the ends of the earth circulated with increasing popularity. This was particularly the case around the time of the Second Council of Lyons (1274), when representatives of the Greek Church formally (if briefly) recognized the authority of the Roman papacy while the papacy carried out diplomatic relations with a Mongol legation.

Generally speaking, the fourteenth and fifteenth centuries were a period of temporary contraction for Western Europe, marked by war, famine, plague, and economic dislocation. Although its prestige was damaged by the period of the Avignon papacy (1309–1378) and the Great Schism (1378–1415), the papacy continued to envision itself as responsible for the reunion

of Christian peoples around the world along with spreading the Christian faith among infidels and pagan peoples. Even some of the most vehement critics of the “decadent” Avignon papacy, such as the Franciscan prophet and biblical exegete John of Rupescissa (ca. 1310–1365), predicted that the future would bring about a union of Greeks and other Eastern Christians, Jews, pagans, and Muslims into a single flock that would be assembled under the spiritual guidance of a transformed and purified papacy. Increasingly, however, the dream of converting the world to the Christian faith was assigned to the rising power of national European powers, such as Spain. Christopher Columbus (ca. 1451–1506) typified this continued fascination with prophecy and apocalyptic thought, declaring on several occasions the belief that his voyages of exploration under the authority of the “Catholic Monarchs,” King Fernando II (r. 1479–1516) of Aragon and Queen Isabel (r. 1474–1506) of Castile, were part of a divinely ordained plan to spread the Gospel among all the peoples of the world and to recapture the holy places of Jerusalem from the Muslims. Although secular notions of progress and the civilization mission came to characterize Western European colonialism and imperialism in the modern era, the idea that the West had a providential role to play in the course of global history would continue to inhabit the European imagination for generations to come.

The Major Pantheons of Mesoamerica

To the ancient Mesoamericans, the earth as well as the creatures and the forces of the natural world were deemed to be linked to sacred gods or forces. The sky, earth, and underworld were especially sacred. In this regard, caves constituted entrances to the netherworld and consequently represented powerful and magic places. Likewise, they looked upon mountains, which bridged the sky and earth, as sacred. Elements of nature, moreover, took center stage in delineating sacredness. Animals such as jaguars, harpy eagles, sharks, caimans, and others consequently were appropriated throughout Mesoamerica as the images of the gods.

The Olmecs developed the first known codified pantheon and religious structure for Mesoamerica. Were-Jaguar, brought about by the mating of a human and a jaguar of the opposite sex, was the principal deity of the Olmec. According to the cultura madre theory, which postulates a mother culture that deeply influences all subsequent cultures, were-jaguars were primarily rain gods, and it was from the Olmec rain gods that all other Maya, Central Mexican, and Zapotec deities were derived. Olmec deities were generally associated with the powerful creatures found in the rain forests such as the snake, harpy eagle, shark, caiman, and jaguar or combinations thereof.

The Rain Baby was undeniably one of the Olmecs’ most important and enduring deities. The

Carving of Quetzalcóatl, one of the most important gods in the Aztec pantheon. (Corel)

► THE POPOL VUH

The *Popol Vuh* (*The Book of the Community*, or *The Council Book*) is the most important sacred text of the Quiché Maya of the Guatemalan highlands to have survived the Spanish Conquest. Originally written in the hieroglyphic script of the Quiché, the text was reportedly compiled by an anonymous native aristocrat in the mid-sixteenth century in order to preserve Quiché cosmological beliefs. The text was subsequently transcribed by another hand into the Roman alphabet. Largely forgotten until the eighteenth century, it was rediscovered when a Spanish friar, Fray Francisco Ximénez, learned of the existence of the manuscript located in Chichicastenango. Fluent in the Quiché language, he translated it into Spanish, and now this version resides in the Newberry Library in Chicago.

The *Popol Vuh* comprises three sections. The first contains the Maya version of the creation of the earth and its first inhabitants. The second relates the epic story of the Hero Twins and their ancestors. The third part elucidates the founding and evolution of the Quiché dynasties up to the Spanish Conquest.

In its first part, the *Popol Vuh* outlines the creation of the earth and the animals that populated it. It relates several attempts to create

humankind and humanity's subsequent destruction because humans forgot their makers, the gods. After this destructive event, the *Popol Vuh* chronicles the stories of the Hero Twins, Hunalpu and Xbalanque. In this epic the Hero Twins defeat the false sun and vanquish the gods of the Underworld. The last and lengthiest section starts with the Ancestral Couple attempting to create a being who would praise the gods. The result was the first four men, ancestors of the Quiché who were fashioned from maize paste. As they praised their divine makers they flourished, yet their near perfection alarmed the gods, who decided to limit their knowledge only to what was nearby or at hand. Subsequently, the founders journeyed to Tulan Zuyua (the Mountain of the Seven Caves), where they encountered the gods and then transported them home in bundles. Balam Quitzé, one of the four primeval men, subsequently received the deity Tohil (the one who gave humans fire) although only after human sacrifice had begun in his name. This epic manuscript closes with a listing of the 14 lineage heads, or generations, from Balam Quitzé down to his descendants in the mid-sixteenth century.

—John S. Leiby

Personified Earth Cave God represented the earth and the entry point into it. The Olmec Dragon was the principal sky god and was apparently derived from a crested harpy eagle. The Sea God personified by a shark appears infrequently in the iconography of the Olmecs. Mystery nevertheless still clouds the precise identification of Olmec gods, and continuing research and analysis will continue for some time to come.

For the Mayan gods, Paul Schellhas was the first to analyze their pantheon through the Dresden, Paris, and Madrid codices. These three Mayan manuscripts, apparently written between 1200 and 1450, continue to be the only authenticated sources depicting the Maya world (in Yucatán) prior to the Spanish Conquest. In developing his analysis, Schellhas delineated the gods found in the codices by a letter designation in order to lessen the chance of ascribing a tenu-

ous or uncertain meaning to the Mayan deities he studied. God A referred to the skeletal god of death with the name of Cizin (flatulent one). God B (called Chac) referred to the Mayan god of rain and lightning, Ku or Chù. God C, according to Schellhas's schema, represented the god of the north star or the personification of sacredness. God D, one of the most important gods found within the Mayan pantheon, was delineated in the form of the aged creator god and usually went by the name of Itzamma. This god was most closely associated with divination and writing. Other important deities included God E (the god of maize), God G (the sun god), Goddess I (the moon god), God K (associated with lightning, fire, and dynastic descent), God L (an important deity of the underworld), and God N (responsible for supporting the sky). In essence, the Maya maintained that the cosmos was dic-

tated by 13 heavens and 9 hells, all controlled by four chief gods who converged at the cardinal points and consequently held up the world.

To the west and north of the Zapotecs, a remarkable people known as the Mixtecs inhabited the mountains. Yet by the thirteenth century, they had penetrated into the Zapotec heartland. Their system of deities was distinct from but clearly influenced by the Toltecs' system of gods. These Indians carved stone beings referred to as *ñuhu*, which were their gods of the earth and vegetation. One of the more important and enduring deities of the Mixtec was a figure called Yahui (a flying figure wearing a fire serpent headdress and a turtle carapace on his back), who most likely was a lightning god probably appropriated from the pantheon of the Zapotecs.

The Mexica, or Aztecs, and nearly all Central Mexican peoples believed in a glorious past that they attributed to the Toltecs, who ruled from Tula. To Central Mexicans of the period immediately preceding the Hispanic incursion, the Toltecs were the originators of all artistry. In fact, the very name "Toltec" was akin to the word "artist" or "craftsman." According to tradition, they were ruled by a fabled monarch named Quetzalcoatl who lived in a great palace, the buildings of which were oriented to the four cardinal directions. In reality, Quetzalcoatl was none other than a god whom the later Mexica appropriated as their own deity.

At the time of the Spanish conquest the Mexica were polytheistic, worshipping a multitude of gods whom they had largely appropriated from other Mesoamerican civilizations. In the Mexica mind, Tezcatlipoca—generally known as the First Sun—was a particularly powerful deity. He was their war god and the god of festivals and was further believed to be a practitioner of black magic. As such, Tezcatlipoca dominated the early Mexica, who especially worried that he would plunge them into perpetual darkness.

The Second Sun according to the Aztecs emanated from the Toltec leader Quetzalcoatl who was apparently transformed into the god of kindness, holiness, and beauty. The Toltecs asserted that he was only a god because of his humane qualities that were invested with a mortal body. In addition, Quetzalcoatl, the Mexica claimed, was the god of the morning star and of wealth.

Tlaloc, the rain god, presided over the Third Sun, and because of his centrality to successful harvests, the Mexica included him in their pantheon, which also symbolized their dominance over Central Mexico. Tlaloc's female counterpart while creating the Fourth Sun was actually dominated by the Mexicas' primary deity, Huitzilopochtli. According to Aztec/Mexica lore, he was their sun god and war god. Both Tezcatlipoca and Huitzilopochtli were akin to one another. Tezcatlipoca was the god of the night sky and warrior of the north, while Huitzilopochtli was the god of the blue sky and warrior of the south.

Cosmological Duality in the Andean World

Duality, the notion that the cosmos, or world, is kept in balance by opposite forces, pervaded the earliest imagery of the Andean peoples, and served as an underlying principle for all aspects of the Inca world, from its kinship systems to the fabric of its government to its religious beliefs and practices. In his *Account of the Ancient Kingdom of Peru* (1613), the native chronicler Pachacuti Yanqui, an Andean of non-Inca heritage, presented a sketch of a great golden altar in the then-destroyed Temple of the Sun at Cuzco that depicted a universe structured in terms of dual oppositions: Sun is parallel to Moon, Morning to Evening, Male to Female, Dry Season to Rainy Season.

A dual system of social organization predated the Incas and still exists in many parts of the Andes, and much, if not all, of Andean oral tradition appears to be structured around dual, opposing, or inverse elements, such as the conqueror and the conquered or the insider and the outsider. A

➤ THE ORIGIN OF THE INCAS

Garcilaso de la Vega (1539–1616), a historian whose Spanish father was a conquistador and whose Andean mother was a cousin of the last Inca kings, relates in his *Royal Commentaries* the legend of the origins of the family of royal Incas, a story that he had often heard from his mother and other Inca relatives. In reading this story, keep in mind that each Inca king was expected to marry his sister, who would serve as primary wife and bear the title of “Coya.” If he had no sister, he married the woman of highest possible rank.

“[I]n olden times, . . . people . . . lived like wild beasts, with no religion or government and no towns or houses, and without tilling or sowing the soil, or clothing or covering their flesh. . . . Our father the Sun . . . took pity and was sorry for them, and sent from heaven to earth a son and a daughter of his to . . . give them precepts and laws by which they would live as reasonable and civilized men. . . . [H]e told them . . . I establish and nominate you as kings and lords over all the people you may thus instruct with your reason, government, and good works. . . . [The son and daughter reach the valley of Cuzco.] Then our Inca said to his wife: ‘Our father the Sun bids us remain in this valley and make it our dwelling place and home in fulfillment of his will. It is therefore right,

queen and sister, that each of us should go out and call together these people so as to instruct them and benefit them as our father the Sun has ordained.’ . . . Thus our imperial city began to be settled: it was divided into two halves . . . upper Cuzco and . . . lower Cuzco. The distinction did not imply that the inhabitants of one half should excel those of the other. . . . All were equal like brothers, the children of one father and one mother. The Inca only wished . . . that the fact that some had been gathered by the king and others by the queen might have a perpetual memorial. . . . In imitation of this, there was later the same division in all the towns, great and small, of our empire.”

According to the legend, the Inca then instructed the men in the crafts of agriculture, irrigation, tool making, and making footwear, and the queen instructed women in the arts of spinning and weaving and other domestic duties.

dual solar cosmology was key to the belief system of the people of Peru’s central coast, where the Sun’s two sons, Pachacamac and Vichama, opposed each other as night and day, respectively. On the north coast the deity Chicopaec was described as the creator, while Aiapaec was identified as the maker. In Huarochirí, the regional cult of the highland male deity Paria Caca was complemented by the female cult of Chaupi Ñamca in the lower valleys toward the coast. Together, their cults constituted a cosmology formed from the essential interaction between coast and highlands.

In Andean myth and history, characters do not necessarily remain static. They can migrate between the opposite categories of *hanan*, a state of male dominance and structure, and *burin*, a state of female subservience and chaos. Thus, the story relating the dispute in 1438 between

Inca Yupanqui and his father, Viracocha Inca, culminated with the deposed Viracocha Inca forced to wear women’s clothing and drink dirty *chicha*, a beer made from maize. Inca Yupanqui (now renamed Pachacuti Inca) assumed the dominant category of *hanan*, while the disgraced Viracocha became subservient. Likewise, the sun cult, patronized by Pachacuti Inca, replaced the previous religious focus of his father on Viracocha, the creator deity, whose name he had assumed upon taking the office of Inca. Whereas Viracocha represented primeval birth, Pachacuti’s male sun symbolized the period of expansion and the height of the Inca state.

Andean and Mesoamerican Sacred Caves

The pre-Hispanic populations of the Andes and Mesoamerica incorporated the natural landscape, especially caves, into their ritual practices, local mythologies, and cosmologies. Andean and Mesoamerican origin stories tell of the emergence of ancestors from caves. Such mythologies no doubt developed from the long-standing use of the numerous caves scattered throughout these varied landscapes and incorporated into the sacred landscape or built environment of many sites.

The minimal records of preconquest Andean beliefs and practices derive largely from the Inca, the ruling population at the time of Spanish arrival and the introduction of writing to South America. The records tell of Inca origin, stories meant to legitimate Inca rulership and to explain social hierarchies among Andean culture groups. While written down after Spanish arrival and thus biased by both the Inca informants and Spanish chroniclers, the stories provide insight into pre-Hispanic Inca worldviews.

The Inca legitimated their rule based in part on myths about their origin in which they claimed to be the first humans to emerge onto earth under the guidance of Viracocha, the creator. The founding ancestors of the Inca, foremost among them Manco Capac, reputedly exited at first sunlight from the central cave at Pacariqtambo, roughly 22 miles (35 kilometers) south of the capital city of Cuzco. In some versions of the myth this cave was connected to an underground pathway that extended from an even more distant and symbolic source, Lake Titicaca in southernmost Peru. In this case the Inca came into being at this mountain lake, which in Andean cosmology was symbolic of the greater sea that encircled but also surfaced within the ter-

restrial mountains. The Inca thus claimed connection to the sun, Inti, who shone on them first in creation, as well as to the sea through connection to the greatest mountain lake of the Andes, Lake Titicaca. From this locale they further linked themselves to the Tiwanaku (100–1200 CE), the preceding Andean culture whose impressive stone monuments still distinguish their ancient lakeside capital city.

The Inca origin myths allude to the symbolic role of caves in Andean thought as conduits for the terrestrial realm and as links to sources of water. Caves worshipped in the Andean landscape are commonly associated with springs, lakes, or even canals. Water is perceived to travel underground throughout the mountains, thus connecting distant locations through association of water sources. Many such conceptions of the world design and the role of caves continue in modern Andean communities.

The principal views of caves found in the Andes, as locations of origin or as sources of water, are likewise encountered in the Mesoamerican region. A number of Mesoamerican myths that survive from the Post-Classic period (1000–1500 CE) tell of a seven-chambered cave from which local ethnic groups emerged. Illustrations of this mythic locale, called Chicomoztoc in Nahuatl, the language of the Aztecs and other Central Mexico populations, appear in surviving post-Conquest codices, or texts. The grottos under the Pyramid of the Sun in the center of Teotihuacán, Mexico, may have recalled physically this mythic cave site as early as 100 CE. The natural cavern formations, which were subsequently altered and enhanced, likely determined the location of the Pyramid of the Sun. The final chambers lie directly beneath the pyramid summit, extending from an access at the pyramid's central stairway. Holley Moyes and James Brady note that a number of sites with man-made caves, which model the seven-chambered cave of Chicomoztoc, occur throughout the Maya Highlands and Central Mexico, thus reinforcing the importance and wide distribution of this origin myth and its physical replication.

In Maya cosmology, the four-cornered terrestrial world may be demarcated by the presence of four directional mountains and a fifth at the center, an ideal by which to model the local

community. Each mountain, or at least ideally the central one, contained a cave. Heyden and other scholars have readily acknowledged the common use of caves and images of caves in naming various Mesoamerican site centers. In fact, the Classic Maya community was termed *chan ch'een*, or “sky cave.” Pre-Conquest and post-Conquest Mesoamerican communities often centered their site on particular caves or *cenotes* (sink holes); these served practically as water holes for the community and symbolically as *axes mundi*.

Caves have received long-standing ritual use in various Mesoamerican practices, given their perceived role as residences for certain deities or as portals to an underworld or otherworld. Such caves, as possible portals, were visually rendered in Mesoamerican iconography through a quatrefoil design. From the time of the earliest Olmec thrones (1000 BCE), which depict elite individuals seated within or emerging from cavernlike niches, Mesoamerican rulership was linked with cave entrances. Palace doorways in some Late Classic (700–900 CE) Yucatan sites were decorated with jaguar mouths, creating the symbolic image of the ruler's emergence from this metaphoric cave opening. During the Late Post-Classic period, Aztec rulers replicated this theme in the impressive rock-cut constructions at Malinalco, in Central Mexico.

Caves in Mesoamerica were closely associated with water, thunder, and rain. Following upon ethnographic work with the Q'eqchi Maya, James Brady has addressed the nature of sacred landscapes in pre-conquest Mesoamerican centers. In one major study Brady focused on the arrangement of the Late Classic Maya site of Dos Pilas, specifically its integration of both large- and small-scale underground caves into the built environment. He demonstrated that the Cueva de los Murciélagos (Bat Cave) was situated directly beneath the most elite complex at Dos Pilas, the Bat Palace. As the point of resurgence for a network of underground channels, the Cueva de los Murciélagos amplified the sound of rushing water at the start of the rainy season into the site complex. This audible hydraulic power presumably was associated with the elite of the Bat Palace and their role(s) in connection to this natural resource.

Many other Mesoamerican centers had caves or cenotes incorporated into their design and

layout. The caves at Dos Pilas evince extensive use as early as the Late Pre-Classic (200 BCE–200 CE), despite the largely Late Classic (700–900 CE) construction and settlement of the site. The Pre-Classic deposits thus speak to the long-standing ritual practice and worship of the caves prior to their integration into the site layout and appropriation by the elite residents. Research into such sacred landscapes and built environments is still relatively innovative in Mesoamerican studies. Undoubtedly, investigations such as those performed at Dos Pilas and Teotihuacán will provide for ever-greater understanding of the role of caves within the visual programs, cosmologies, and sociopolitical structures of the Mesoamerican region.

Ball Games North of the Rio Grande

Traditional ball games have been and continue to be key cultural elements for many Native peoples throughout the Western Hemisphere. Many of the ball games and their associated traditions

differ, and the ball games offer different meanings in different contexts. Ball games have been the focus of ritual religious activity in some communities and on occasion have been associated with healing practices. In some communities they have served primarily as social events that are part of both religious and secular festivals, and in some cases they have had no apparent sacral meaning.

The earliest account of a ball game written by a European comes from the *Jesuit Relations*, in which in 1636 Jean de Brébeuf wrote about the game occurring in the area then known as New France. He said that a Huron medico-religious specialist, whom he characterized as a “sorcerer,” might prescribe a game of “crosse” for the benefit of the entire nation or for a sick individual, and sometimes a person would dream that a game was necessary for recovery from illness. Racket and ball games were the most widespread of those ball games that had explicit associations with Native American religious systems.

Research suggests that Native peoples have played many different types of ball games, including double ball, shinny, and games that employ rackets now widely known as “lacrosse-type,” as well as engaging in ball racing and ball throwing. Racket games in general, and specifically those versions played by communities in what is now the northeastern United States and southeastern Canada, are generally considered to be the precursors to the sport of lacrosse. At one time indigenous groups that played racket and ball games included many along the Eastern Seaboard of North America and across the inland Southeast, as well as in the Great Lakes region and surrounding areas. A few tribes in present-day California and the Pacific Northwest region of North America also played versions of the game.

Many Native American communities have preserved accounts of ball games in cultural narratives in which nonhuman beings played against humans, or in some cases against each other in a time before humans inhabited the earth. In the Cherokee narrative tradition there are accounts of ball games played by supernatural beings (the Sons of Thunder) and games between teams of birds and four-legged animals, as well as famous games between Cherokee teams and teams from other nations. Choctaw, Muskogee, Seminole, Mohawk, and Onondaga narratives of similar games

between birds and animals exist, and in all the pivotal figure of the bat is rejected by one or both of the teams before being allowed to play. The narratives differ regarding such details as which team finally accepted the bat and why, but the team that did so always wins in the end.

Major Religious Traditions in Oceania

Oceania, a region comprising most of the islands in the Pacific Ocean, including Australia, New Guinea, Island Melanesia, Micronesia, and the Polynesian Triangle of Hawaii, New Zealand, and Rapa Nui (commonly known as Easter Island), is home to a diverse array of cultures, thousands of languages, and an equal variety of religious practices. The range of religions in Oceania prior to the arrival of European missionaries in the eighteenth century, many of which are still practiced today, included everything from ancestor worship and belief in the supernatural power of nature in places such as Australia and New Guinea to official state-level religious practice in the kingdoms of Hawaii.

➤ TABOOS

The term “taboo” is used commonly in modern Western culture to refer to that which is forbidden, or off-limits, both physically and ideologically. Few people know that this term has ancient roots, which can be traced back linguistically to the ancestral Proto-Oceanic (*Tabu*) and Proto-Malayo-Polynesian (*Tabus*) languages from many of the contemporary languages of the Pacific Islands (for example, *kapu* in Hawaiian). The concept of taboo or *tapu*, along with *mana*, formed one of the core concepts in almost all Oceanic religions. Based on deep religious beliefs, taboos structured many aspects of daily life in Oceania. More than dictating what was off-limits, taboos were about determining what one did to ensure that the universe was ordered appropriately. Taboos determined, among other things, whom one could marry, when certain resources could or could not be harvested, and even when, what, and with whom people ate. For example, bananas, pork, and certain kinds of fish were off-limits for Hawaiian women, while the belief in the importance of upholding *kapu* in food preparation can be seen archaeologically in Hawaiian house compounds (*kau hale*), which often have separate cookhouses for men and women, especially in chiefly houses.

—James L. Flexner

Two important concepts that are pervasive in Oceanic religions are *mana* and *tabu* (*taboo*). *Mana* is a concept that is almost universal to Oceanic religions and can be taken to mean “spiritual or supernatural power,” though the term may mean more specific things in different contexts. Other important aspects of Oceanic religion are worship of ancestors or ancestral spirits and the belief in supernatural power dwelling in the natural world. Materially, upright stones are commonly involved in Oceanic religious rituals, as is the consumption of kava (*Piper methysticum*), a plant with mild narcotic properties whose use can be traced to ancestral Polynesian rituals. While some general patterns are consistent across time in Oceanic religions, several unique developments can be traced to the period spanning roughly 1000–1500 CE, especially in Polynesia and Micronesia. This is not to

say that religious practices in Australia and Island Melanesia were somehow static; rather, archaeological evidence for monumental architecture reveals a different understanding about religious practices in the past than can be inferred from contemporary ethnography. Future research may produce a clearer picture of religion in these areas during the period in question, especially in Island Melanesia.

The continent of Australia was first settled at least 40,000 years ago during the Pleistocene era. Australian Aboriginal religions are themselves very diverse. Australian Aboriginal peoples speak some 200 languages that share similarities, as do their religions. Australian Aboriginal religions are distinctive when compared with the rest of the world’s religions but also very distinct among themselves. Because of the great time depth involved, it is difficult to base interpretations of ancient religious practices on observations of living people. However, there is evidence that many Australian Aboriginal people continue to use rock art sites that are thousands of years old for religious purposes, and many documented traditions appear to have great antiquity, notably bark painting, which sometimes shares motifs with rock art and which can refer to ancient landforms and historical events. While observed Aboriginal religious practices are absolutely not the same today as they were many millennia ago, certain common characteristics may have derived from more ancient practices.

One of the most important characteristics of Australian Aboriginal religions is a belief in a concept usually called the Dreaming in English (obviously each Aboriginal language has its own name or set of names for this concept). The Dreaming consists of an interconnected set of meanings, including beliefs about the creation of the world by ancestral beings, the continued presence and power of those beings in the landscape, a way of life couched in a morality and set of rules based on these beliefs, and a person’s place within this cosmology. The Dreaming is both about an understanding of the past, how the world came to be, and the present, how the world works based on the logic of how it came to be and continues to emerge. The diversity of environments on the Australian continent, which range from sandy deserts in the interior to tropi-

cal rainforests in the northeast to mild forested landscapes in the southeast, also contributes to the diversity of Aboriginal religions because they are tied so closely to the natural world.

The religions of Melanesia, also widely documented by ethnographers, are even more diverse than those of Australia. The island of New Guinea alone may have contained thousands of different languages before European contact, especially in remote highland valleys. This diversity makes it particularly difficult to identify religious practices in the past, though certain common strains of religious thought may hint at structural elements of Melanesian religions. One such structural characteristic is a belief in the presence of supernatural beings in the natural world, though the specific beliefs are widely variable. Another common characteristic is the relationship of warfare to ritual cycles, especially between different social groups. As in Australia, it is usually extremely difficult to attribute specific religious practices or beliefs observed in the present in places such as New Guinea to past societies in anything but the most general terms.

In Polynesia, archaeological evidence points to a variety of religious developments that grew out of an Ancestral Polynesian religious system. Anthropologists Patrick Kirch and Roger Green reconstructed this system based on linguistic, ethnographic, and archaeological evidence. Included among the archaeological remains of religious practices are monumental works of stone, perhaps most famously the stone heads, or *moai*, of Rapa Nui, which are unique in the region. The scale of religious construction projects can be related to the rise of more hierarchical societies in Polynesia, often called chiefdoms. In some places such as the Marquesas, where massive sacred plazas have been recorded, Polynesians constructed raised stone altars, or *ahu*. Polynesian chiefdoms with more rigid hierarchies often developed some of the more elaborate religious structures, such as the Tahitian *marae* or Hawaiian *heiau*. Oral traditions and archaeology suggest that contact between Tahiti and Hawaii occurred between 1000 and 1300 CE, possibly mutually influencing religious development, after which the two cultures developed separately. Religious practices in Hawaii were especially

highly structured, linking the annual Makahiki cycle to tribute collection for the Hawaiian chiefs. In Hawaii and among the Maori of New Zealand, ritualized cycles of revenge, carried out on a larger scale than those observed in Melanesia, were connected chiefly to competition over land, and these cycles can be traced to the construction of *pa* (hill forts) in New Zealand. Hawaiian temples, called *heiau*, became places where sacred cosmic events were intertwined with the historical and mundane.

Finally, one of the most striking conjunctures of historical events, religious belief, and monumental construction in all of Oceania occurs at Nan Madol, a massive complex of artificial islands with megalithic constructions of prismatic basalt built off of Pohnpei Island in Micronesia. The site was constructed during the Saudeleur dynasty (roughly 1200–1600 CE) as a religious center. Saudeleur rituals included turtle sacrifice and worship of a sacred eel kept in one of the islets of Nan Madol. Other examples of megalithic temples dating to this period have been documented elsewhere on Pohnpei, suggesting a widespread official religion under the Saudeleur. According to legend, the Saudeleur dynasty met its end when the last ruler tried to capture one of the gods, Nan Sapwe, only to be defeated by Isokelekel, the son of Nan Sapwe, and 333 warriors, bringing in a new age and a different way of life in Pohnpei.

■ Introduction: Aristotelianism—Acceptance, Rejection, Accommodation

Although Aristotle (384–322 BCE) was a pagan who had lived centuries earlier, his writings constituted the single largest and most authoritative body of knowledge and wisdom inherited from Greek antiquity so far as many Islamic, Jewish, and Latin Christian thinkers were concerned. Aristotle had put his mind and writing stylus to many subjects, such as biology, botany, theoretical physics, meteorology, zoology, theater, rhetoric, music, political theory, and poetry, but it was his philosophy, especially logic (the art of critical analysis), metaphysics (theoretical philosophy that focuses on the nature of Being), and ethics that most captivated theologians within the Abrahamic tradition, namely Jews, Christians, and Muslims.

A significant number of medieval Muslim, Jewish, and Christian theologians accepted Aristotle's system. They included the Andalusian Ibn Rushd (1126–1198, in Latin "Averroes"), a polymath who is generally regarded as the greatest of Islam's many great medieval scholars and thinkers; Moses ben Maimon (1135–1204, in Latin "Maimonides"), acknowledged as the greatest Jewish thinker of the Diaspora; and Thomas Aquinas (1225–1274), the Roman Church's "Angelic Doctor" whose voluminous works have had a lasting impact on Catholic theology. Indeed, Aquinas and many other Latin Christian theologians of his age were so impressed by Aristotle that they consistently referred to him not by name but reverentially as "*ille philosophus*" (the Philosopher). Moreover, Aquinas and his peers acknowledged their debt to Ibn Rushd's voluminous commentaries on Aristotle, which had been translated from Arabic to Latin, referring to him respectfully as "the Commentator." Maimonides was equally indebted to Ibn Rushd's insightful commentaries, and he in turn influenced Aquinas's thought.

Acolytes such as Ibn Rushd, Maimonides, and Aquinas were predisposed to accept as definitive anything written by or ascribed to Aristotle as long as it did not contradict Divine Revelation and dogmatic Faith. But there was the problem. Aristotle had espoused several theories that con-

tradicted the shared beliefs of Jews, Christians, and Muslims. His ordered universe allowed no room for the intervention of Divine Providence and miracles. He also denied personal immortality. Just as serious, he taught that matter and, therefore, the cosmos are eternal. To the contrary, the Abrahamic tradition holds as sacred truth the belief that God created the universe out of nothing, that God has intervened in human affairs at special moments in history and has suspended the laws of nature to perform miracles, and that the physical cosmos will one day be destroyed, in keeping with the Divine Plan. Both the Christian and Islamic faiths also firmly hold to the dogma of personal immortality, whereas Jewish opinion is divided on the issue. For theologians, who were so captivated by the elegance and coherence of the Aristotelian system, the question was: How might it be accommodated to Revelation? For those who saw this pagan philosopher-scientist as a threat to the Truth, the question was: How might we best protect the Faith from his pernicious influence?

As the entries under this topic illustrate, the struggle to accommodate Aristotelianism to the Abrahamic faiths was a messy process. Moreover, in the end Islam and the Latin Church followed two separate paths and reached different solutions.

—*Alfred J. Andrea*

Arab and Jewish Aristotelians

The development of Islamic (or Arabic) and Jewish philosophy, especially after 1000 CE, would have a tremendous impact on the medieval scholastic philosopher-theologians of the Latin West in the thirteenth and fourteenth centuries. In both cases, Muslim and Jewish philosopher-theologians attempted to integrate ancient Greek thought, especially the teachings of Aristotle (384–322 BCE), into monotheistic systems of belief, thereby balancing reason and revelation. Their efforts profoundly influenced European Christian thinkers, who acknowledged their debt.

Islamic philosophy developed first in the eastern Islamic lands before 1000 and then in Muslim Spain, reaching its zenith in both areas after 1000. The height of Islamic philosophy in the Muslim East was reached by Abu Ali al-Husain ibn Sina (980–1037), a Persian known to the West as Avicenna. Although he was most well known as a physician and for his medical writings, he is nevertheless regarded as the greatest philosopher of the Islamic Peripatetic School, which combined Aristotelian and Neoplatonic thought. His *Book of Healing* is considered the best elucidation of Aristotle produced in the early eleventh century. Ibn Sina was influenced greatly by *On the Objects of Metaphysics* by Abu Nasr al-Farabi (ca. 870–950), one of the first Islamic philosophers to comment on the works of Plato and Aristotle. One of Ibn Sina's most significant contributions to philosophy was his discussion of Being, which may have been influenced by discussions of Being in *kalam*, orthodox Islamic speculative theology. He maintained that with the exception of the Necessary Being (in which essence and existence are one), there is a division in Being between essence and existence. Moreover, there are degrees of Being, beginning with God and moving down the (Neoplatonic) hierarchy of Being to the material world. In all things outside of the Necessary Being, existence is separate from essence, and such beings are only possible beings unless or until they are brought into existence by the Necessary Being. This Being is itself one and simple, and Ibn Sina identified this as Allah. Ibn Sina's metaphysical proof for the existence of the Necessary Being is that there cannot be an infinite regression of merely possible beings that exist, otherwise nothing would have come into existence.

For Ibn Sina, creation is necessary and eternal, which was at odds with the Islamic doctrine of creation. Regarding the immortality of the soul, Ibn Sina was likewise at odds with Islamic doctrine because although he maintained that all human souls survive, he taught that the body cannot be resurrected.

Such unrestrained rationalism in the Sunni world was met by a counterattack led by Abu Hamid Muhammad al-Ghazali (d. 1111), author of *On the Incoherence of the Philosophers* that was directed primarily against Ibn Sina's philos-

ophy. Al-Ghazali, who embodied a union of Asharite theology, which employed modified Greek logic to elucidate the truths of the Quran, and mystical Sufism, was a formidable opponent because of his grounding in both Greek logic and Islamic spirituality. After al-Ghazali's attack, the study of philosophy declined among Sunnis in the Islamic East, although the Eastern Shias were more amenable to the use of philosophy in religious discussions. In the West, however, particularly in Al-Andalus (Muslim Spain), philosophy flourished among Jews and Sunni Muslims.

One of the most important Andalusian Jewish philosophers was Solomon ibn Gabirol (ca. 1021–ca. 1057), known in the Latin West as Avencebrol or Avicebron. His Neoplatonist philosophy, which is found in *The Fountain of Life*, a work written originally in Arabic and then translated into Latin in the twelfth century, influenced a number of leading scholastic philosophers in thirteenth-century Latin Christian Europe, especially the Franciscans' leading theologian, Bonaventure. Gabirol's system, which was predicated on a doctrine known as universal hylomorphism (universal material forms), maintained that matter and form (or spirit) are inseparable and are found throughout the universe, even in incorporeal things. Gabirol maintained that matter is part of everything except God and emanates from the divine Will, forming the foundation for subsequent emanations, the lowest of which is the corporeal world. Humanity is the microcosm of the universe, meaning that all of the primary characteristics of the cosmos are also found in humans, whose ultimate end is to know the divine Will. His thought was criticized by Jewish scholars as non-Jewish, while many Christians thought him a Christian.

The first Islamic philosopher of note in Spain was Ibn Bajjah (ca. 1070–1138), known in Latin as Avempace. In his two major works, *The Regime of the Solitary* and *Treatise on the Union of the*

Ibn Sina, known to Latin Europeans as Avicenna, was among the foremost medieval Muslim philosophers and physicians. (Library of Congress)

► THE HERESY OF IBN RUSHD

In 1195, due to conservative religious influences at court, Ibn Rushd and other philosophers in Muslim Spain were accused of heresy. Ibn Rushd was forced into exile and his writings ordered burned, but he was only briefly out of favor and returned to Marrakesh, where he died in favor in 1198. In his works concerning religion, the most important of which was *The Decisive Treatise Determining the Nature of the Connection between Religion and Philosophy*, and in his *The Incoherence of the Incoherence* (against Ibn Sina, as well as al-Ghazali), he took pains to demonstrate how religion and philosophy do not necessarily conflict. In these works he expressed belief in the resurrection of the body, although it was a different but identical body. Nevertheless, in his strictly philosophical works, he appears to have maintained heretical positions, such as the eternity of the cosmos and the necessity of creation (hence, no miracles are possible); that the Material Intellect, which survives the body at death and returns to the Agent Intellect, is the same for all people; and although there is no individual immortality, the human species as a whole lives on eternally through the Material Intellect.

—Kimberly Georgedes

Intellect with Man, he primarily addressed the question: How best does one obtain the Ultimate End, which is to know and love God? Unlike most other Islamic philosophers, Ibn Bajjah maintained that the best way to reach this goal is outside of society, living a solitary life and pursuing knowledge of the forms through actualizing one's potential intellect so that it becomes the acquired intellect. For Ibn Bajjah, one obtains the ultimate end when the acquired intellect is absorbed into the Agent Intelligence. His contributions were unique so far as Islamic thought was concerned in that he maintained that the quest for beatitude can be achieved not only outside of society but also without revelation.

Abu al-Walid ibn Rushd (Averroes in Latin), who was born in Cordova in 1126 and died in 1198, was trained as a jurist and physician. In 1168 he was introduced to the Almohad ruler

in Marrakesh, Morocco, Abu Yaqub Yusuf, who in 1169 requested that Ibn Rushd begin commenting on Aristotle and appointed him as a judge in Seville. In 1171 Ibn Rushd was appointed judge of Cordova, and in 1182 he became court physician. His philosophical works were very influential, more so in the Christian West than in the Muslim East. (Most of his works survive only in Latin or Hebrew copies.) To Latin scholastic theologians and philosophers he was known simply as “the Commentator.” The purest Aristotelian among Muslim philosophers, he wrote 38 commentaries on various Aristotelian works. He also wrote treatises, particularly on physics and epistemology (the study of the nature of knowledge), and two defenses of philosophy against al-Ghazali's *On the Incoherence of the Philosophers* and the attacks of other conservative Islamic theologians. Ibn Rushd believed that both reason and revelation are sources of truth and lead to the same end, that there is harmony between revelation and reason, and that the Quran encourages those with the intellectual capabilities to study philosophy. He maintained, however, that for those incapable of reasoning rigorously, the Quran suffices as the source of truth. Indeed, he argued that philosophy should be hidden from those incapable of understanding it, as it would only harm their faith.

Ibn Rushd responded with his *On the Incoherence of the Incoherence*, to al-Ghazali's *On the Incoherence of the Philosophers*, although Ibn Rushd's work did not have a great impact on the Islamic East. His thought was more rationalistic and less metaphysical than that of Ibn Sina, and Ibn Rushd was considered less congenial to Muslim thought. He rejected Ibn Sina's metaphysical arguments for the existence of God, arguing that the existence of God can be proved only through physics, specifically via causality, extrapolating back via cause and effect to the Prime Mover. In essence, Aristotle's proof for a Prime Mover, or First Cause, found in Book 8 of his *Physics*, was for Ibn Rushd the only demonstrable proof. He also rejected Ibn Sina's division of Being into essence and existence as well as the Neoplatonic idea of creation by emanation but argued that all of the Intelligences and their motions are created directly by the First Being.

Ibn Rushd was the last of the great Aristotelian philosophers in the Muslim tradition.

Moses ben Maimon (1135–1204), known as Maimonides but also as Athe Rabbi, was the most important and influential Jewish philosopher-theologian of the Middle Ages. Born in Cordova, Spain, he died in Cairo, Egypt, where, like many philosophers in the Islamic world, he made his living as a physician. His most famous work is *The Guide for the Perplexed*, which he wrote to remove the doubts of Jews concerning the nature and relation of religion with science, philosophy, and the traditional Talmud. Primarily a theological treatise, its purpose was to find harmony among theology, Jewish revelation and tradition, and philosophy. He maintained that most men should not study philosophy and argued that moral virtues must precede the study of philosophy. He also criticized Islamic *kalam* as well as Aristotelian science. He argued that *kalam* is internally defective, often accepting philosophical arguments merely because they agree with religious teachings. Moreover, he maintained that Islamic theologians who engaged in *kalam* failed to adequately explain creation out of nothing. Likewise, he maintained that Aristotle's arguments for the eternity of the world were insufficient. Much more than just a negative critic, however, Maimonides presented several proofs from reason for the existence of God that were similar to those of previous thinkers but that significantly served as the most direct source for Thomas Aquinas's famous proofs. Maimonides' cosmology was similar to that of the Muslims as well, although depending on the type of work he was writing he appears to have held both that the world is eternal and that it was created by God.

In an age that witnessed crusades, jihads, and pogroms of Jewish communities by some Christian and Islamic communities and leaders, theologian-philosophers of these three Abrahamic faiths were struggling with similar conundrums as they attempted to reconcile the best science and rational philosophy available to them with the monotheistic doctrines of their respective religions. In the process, Islamic and Jewish thinkers profoundly influenced the development of Western rationalism.

The Early Application of Logic to the Christian Faith

The late tenth and eleventh centuries saw an intellectual revival in the Latin West that began in the monasteries and cathedral schools but became the hallmark of its new universities by the mid-twelfth century. Known generally as Scholastic philosophy, this was a method of rational analysis applied to theology and canon, or church, law that became the hallmark of the scholastics, or teachers, of Europe's schools.

This revival began with the study of basic Aristotelian texts on logic as translated and commented on by the sixth-century Christian scholar Boethius (d. 526). Early key figures in the recovery and use of logic in the West include Gerbert of Aurillac (ca. 946–1003), who headed the cathedral school at Reims, whose great interests were dialectic (logical argumentation) and mathematics, and who ended his life as Pope Sylvester II (r. 999–1003). His pupil Fulbert of Chartres began the cathedral school at Chartres, where he set in place an important literary and philosophical program of studies. Berengar of Tours (ca. 1010–1088), a pupil of Fulbert, attempted to explain the Eucharist in terms of the Aristotelian categories, which was opposed by, among others, Lanfranc (1005–1089) of Bec (and later archbishop of Canterbury) and the Italian monastic reformer St. Peter Damien (1007–1072), the latter of whom opposed the use of dialectic and rationalism in theology in general. Although Berengar's views were condemned by the Church,

➤ SELECTION FROM ABELARD'S *SIC ET NON*

In the following passage, Abelard introduces and justifies the scholastic method that would set the standard for Western advanced education for generations:

“Among the multitudinous words of the holy Fathers some sayings seem not only to differ from one another but even to contradict one another. Hence it is not presumptuous to judge concerning those by whom the world itself will be judged. . . . In view of these considerations we have undertaken to collect various sayings of the Fathers that give rise to questioning because of their apparent contradictions. . . . This questioning excites young readers to the maximum of effort in inquiring into the truth, and such inquiry sharpens minds. Assiduous and frequent questioning is indeed the first key to wisdom. Aristotle, that most perspicacious of all philosophers, exhorted the studious to practice it eagerly, saying, ‘Perhaps it is difficult to express oneself with confidence on such matters if they have not been much discussed. To entertain doubts on particular points will not be unprofitable.’ For by doubting we come to inquiry; through inquiring we perceive the truth, according to the Truth Himself.”

Abelard then poses 156 questions that compel students to entertain both supporting and opposing arguments to suppositions such as “God is one,” “God can do all things,” and “Peter and Paul and all the apostles were equal.”

Peter Abelard, “Sic et non,” trans. Brian Tierney, in *Great Issues in Western Civilization*, 2nd ed., ed. Brian Tierney, Donald Kagan, and L. Pearce Williams (New York: Random House, 1972), 1:412–414.

nevertheless his impact on the application of dialectic to theology was significant, particularly concerning the theology of the Eucharist.

Arguably the two most important thinkers of the eleventh and twelfth centuries, however, were St. Anselm of Canterbury and Peter Abelard. Anselm (ca. 1033–1109), a northern Italian who eventually became archbishop of Canter-

bury, is known as the Father of Scholasticism because of his use of logic without reference to divine Revelation to prove the existence of God. Two of his greatest works were the *Monologion* (1077) and the *Proslogion* (1078). The former was written at the request of his monks, who wanted a proof for God’s existence based on reason alone, and sets forth several proofs for God’s existence based on value theory (i.e., if there is a good and a better of something, there must be a best, and the Ultimate Best is God). The *Proslogion* contains the famous Ontological Argument for God’s existence, which continues to be criticized and defended by philosophers to this day. Anselm’s basic argument was that if one accepts the definition of God as that than which nothing greater can be thought or conceived, it cannot exist only in the understanding; it must also exist in reality, because if it exists only in the understanding, it can be thought to exist in reality, and this is greater. Moreover, if it existed only in the understanding, then that than which a greater cannot be conceived is that than which a greater can be conceived, which is a contradiction. Therefore, it must exist in reality (*Proslogion*, chap. 2). Anselm is also known for *Cur Deus Homo* (*Why God Became Man*, 1092) concerning the Incarnation and atonement. His attitude toward theology was “I believe in order that I may understand,” which would be countered by Abelard’s attitude that doubt leads to inquiry and inquiry leads to the truth, including the Perfect Truth—God.

Peter Abelard (ca. 1079–1142) was well known for his teaching, stormy disputes, and tragic affair with his student Heloise (which he chronicled in his *History of [My] Calamities* as well as his letters). His career as a master philosopher-theologian began, characteristically, with his disagreement with two of his contemporary leading logicians, Roscellinus and William of Champeaux, regarding the issue of “universals,” general terms used to describe an entire class of individual entities, either concrete items, such as “dog,” or abstractions, such as “beauty.” Roscellinus took an extreme nominalist position, arguing that a universal is simply a name (*nomen* in Latin) and has no existence apart from the specific objects it describes. Put another way, universals exist only in the mind of the person who finds commonali-

Peter Abelard tutors his student and wife, Heloise, from a fourteenth-century French manuscript. (Giraudon/Art Resource, NY)

ties among disparate objects. William of Champeaux, to the contrary, took an extreme realist position, arguing very much like Plato many centuries earlier that universals have a real and separate existence apart from the particulars to which they give form and apart also from the mind of the person who perceives them. Abelard assumed a middle position, called by some scholars conceptual realism, reaching essentially the same conclusion as had Aristotle centuries earlier but without knowledge of the Greek philosopher's solution because Aristotle's *Metaphysics* was not yet available in Latin translation. Although his position is much more complex than this, according to Abelard universals are necessary creations of the intellect because they exist not before the thing is perceived (the realist position) and not only after the thing is perceived (the nominalist position), but rather they exist inherently in the thing. That is, universals are

concepts in the mind (which are not things in themselves) that correspond to the essential qualities of the entities they describe.

This controversy was no idle game of words because the issue of universals stands at the heart of Christian theology and ethics. Are there virtues such as love or only loving acts? If the latter, how can the Gospel say "God is love"? Is there such an entity as the Church or only individual Christians? If one accepts that there is a universal Church, does it follow that it existed from all eternity? Did not Christ institute the Church? Abelard's answer to this conundrum set the stage for future discussions on this key issue in Western Christian thought.

His application of logic to theological problems was also significant to the development of the scholastic method of posing a question and marshaling authorities for and against and testing the weight of those authorities. This is the method he used in *Sic et non* (*Yes and No*, ca. 1121–1122), a sourcebook of conflicting authorities on a variety of theological issues. The text was designed to have his students apply logic and critical analysis in addressing theological questions. Abelard posed no solutions himself because he wished to challenge his readers, and his approach alienated some conservative church leaders. Nevertheless, his method greatly influenced later writers, such as Peter Lombard, whose *Four Books of Sentences* (1150–1152) became the standard textbook in theology second only to the Bible, and Gratian, whose *Decretum* or *Concordance of Discordant Canons* (ca. 1140) became the basic text for the study of church law. The scholastic method, which revolved around the challenge of resolving posited questions, became the West's dominant method of advanced instruction in the generations following Abelard. He was also known for his *Scito te ipsum* (*Know Yourself*, ca. 1136–1140) in which he argued for an ethics based on intent, not result.

Abelard's ideas on the Trinity were condemned, and St. Bernard of Clairvaux (the major exponent of the time of a form of monastic theology that emphasized love and compunction and meditating on the Bible in order to understand its truths, as opposed to subjecting it to logical analysis) was an ardent opponent of Abelard and was instrumental in his condemnation

at Sens in 1142. Nevertheless, the trend of rationally analyzing and systematizing theology would continue and lead to greater accomplishments in the thirteenth century.

The Rebirth of Aristotelian Philosophy in the Latin West

With the Latin West's recovery of the majority of Aristotle's works from the late eleventh century into the thirteenth century, Christianity once again had to deal with Tertullian's famous question, which he posited about 1,000 years earlier: "What has Athens to do with Jerusalem?" Western Christendom was now faced with a large, logically consistent body of material that contradicted many significant Christian doctrines including such issues as the necessity of creation, the eternity of the world, and the immortality of the soul. Moreover, Latin Christian scholars were faced with commentaries on Aristotle by Muslims and Jews that would have to be dealt with as well. A huge task of sifting and assimilating awaited the Christian scholastics of the late twelfth and thirteenth centuries.

These newly discovered works of Aristotle were recovered primarily through translations into Latin from Arabic translations, and Spain, where Islam and Christianity met along ever-shifting borders, was the center of transmission. Toledo, which had been captured by Christian forces in 1085, was the main center for two translation programs. One was initiated by Gerard of Cremona (1114–1187), who began a program of translating Aristotle along with his Arabic commentators (approximately 70 translations altogether), including al-Farabi (d. ca. 950), Ibn Bajjah (d. 1138, known in Latin as Avempace), and Ibn

Rushd (1126–1198, known in Latin as Averroes). The second program was that of Dominicus Gundisalvi (fl. 1162–1190), who directed the translation of various works more favored by Jewish scholars, primarily those of Ibn Sina (980–1037, known in Latin as Avicenna) and his tradition. In the thirteenth century Michael Scot, a Scotsman working in Sicily, and Hermanus Allemanus (Herman the German) brought the two traditions together in their translations. During the thirteenth century, some Western scholars also began to study and translate from the original Greek texts. James of Venice and Burgundio of Pisa translated Aristotle's books on natural philosophy from the Greek while they were in Constantinople in 1136. Additionally, William of Moerbeke (ca. 1220–1286), arguably the most important of the translators, revised some of James's translations and made many more (approximately 50) from the Greek.

This recovery of the works of Aristotle, particularly the logical works of the *Organon* (*The Prior Analytics*, *The Posterior Analytics*, *The Topics*, and *Sophistical Refutations*), which became known as the New Logic (whereas the few Aristotelian works previously made available to the Latin West by Boethius in the early sixth century were now known as the Old Logic), redefined Western Christian Europe's educational system, particularly in the nascent universities of Paris and Oxford in the thirteenth century. Aristotle's works on moral philosophy, such as his *Nicomachean Ethics*, on natural philosophy (what is called science today), such as *Physics* and *On Corruption and Generation*, and on metaphysics, such as his *Metaphysics* and *On the Soul*, were also translated in whole or part.

Richard Rufus of Cornwall, a Franciscan at Oxford, was probably the first to comment on Aristotle's *Physics*. William of Auvergne, a secular master at Paris and bishop of Paris from 1228, used both the works of Aristotle and Avicenna, although he rejected Aristotle's concept of the eternity of the world and Avicenna's determinism as well. William of Sherwood, who taught at Paris and then Oxford (1252), was the first to make an impact on the New Logic with his *Introduction to Logic* and greatly influenced later logicians, including Peter of Spain (later Pope John XXI, r. 1276–1277), who wrote the most

popular text on logic. Robert Grosseteste, bishop of Lincoln, although more of an Augustinian and Neoplatonic thinker himself, was also a translator of Greek writings, and in 1246–1247 he made a complete translation of Aristotle's *Ethics*, along with Latin translations of many Greek commentaries on the work, and commented on the *Posterior Analytics*. Grosseteste's impact on thirteenth-century thought was considerable not just for his translations.

Among the religious orders in the universities, the Dominicans in general tended to be the most favorable to the thought of Aristotle. The two most famous Dominican Aristotelians, both of whom were masters of theology in Paris, were the German St. Albertus Magnus (Albert the Great, 1193/1206–1280), known for his encyclopedic learning and translations, and his student the Italian St. Thomas Aquinas (ca. 1225–1274). Thomas is known for his *Summa Theologiae* (*A Compendium of Theology*), thought by many to be the apex of medieval Christian thought and the greatest synthesis between Aristotelianism and Christianity and probably intended to be a textbook for young Dominicans in their provincial schools, prior to university study, as well as for his *Summa contra gentiles* (*A Compendium in Opposition to the Heathens*) and his “Five Ways” of proving the existence of God. Although Dominican theologians tended toward Aristotelianism, they rejected and condemned the errors of Latin Averroists in the Arts Faculty at the University of Paris, who preferred to accept and study Aristotle on his own terms without reference to theological parameters and limitations. The Dominicans also tended to emphasize apologetic theology, that is, arguing persuasively against non-Christians. This was likely the primary purpose of Aquinas' *Summa contra gentiles*, which attempted to prove basic certain Christian doctrines through logic and reason alone.

The writings of Aristotle were not wholeheartedly accepted initially, and assimilation was slow and not without resistance, especially concerning the works on natural philosophy and particularly at the University of Paris. Nevertheless, by 1255 students in the Arts Faculty at Paris had to hear lectures on all of his available works on logic, ethics, metaphysics, and natural philos-

➤ AQUINAS AND ISLAMIC AND JEWISH THINKERS

The influence of Thomas Aquinas on Catholic thought, particularly since the Reformation, has been incalculable, and although many understand the influence of Aristotle on Aquinas, the influence of Islamic thinkers such as Ibn Sina (Avicenna), Ibn Rushd (Averroes; i.e., the “Commentator”), and the Jewish rabbi Moses ben Maimon (or Maimonides, 1135–1204) on Aquinas is just as profound. Far from accepting Averroes' interpretation of Aristotle outright, particularly regarding Averroes' interpretation of Aristotle's views on the intellect, Aquinas' views on Aristotle were also affected by Platonism, including Avicenna's Platonized Aristotelianism. Indeed, from Ibn Sina, Thomas gained the distinction between the one Necessary Being and possible being that allowed him to come to his insight regarding his metaphysics of being between essence and existence. Maimonides also influenced Aquinas in a number of ways, not the least of which was in how to converse with adherents of another religion. Maimonides also was probably a source for Aquinas's “Five Ways” for proving the existence of God through reason alone. For example, the first way is based on change, or movement. Whatever moves is moved by another, but there cannot be an infinite regression of movement; otherwise, nothing would be moved. Therefore, there must be an unmoved first mover or an unchanged agent of change, which “everyone” understands to be God. The second way, similarly, is based on cause and effect, the third way on contingency and necessity (possible and necessary beings), the fourth way on degrees of perfection, and the fifth way on teleology, that is, Aristotle's view that everything has its proper or final end, which indicates an order in the universe that in turn indicates an intelligence that orders each thing to its proper or final end.

—Kimberly Georgedes

ophy. This new focus on Aristotle's logic and natural philosophy at Paris, Oxford, and elsewhere gave initial impetus to the rise of a new European empiricism and science. Logic became central to education along with speculative grammar and linguistic analysis. Aristotle's empirical emphasis and his emphasis on the

inseparability of form and matter began to replace the Platonic emphasis on form and matter as separate entities and the real world being that of forms or archetypes, as opposed to the unreal phenomena that we sense in the physical world (i.e., the question of universals). Rhetoric remained strong at Bologna, however, since it was connected to law. Even in the faculty of Theology, though to a lesser degree than in Arts, Aristotle became a source of authority, known simply as “The Philosopher,” and Averroes was “The Commentator.” This declined somewhat in the fourteenth century due to the condemnations of 1277, although logic remained central to theology.

The Rejection of Aristotle and the Condemnations of 1277

Aristotle's works had a great impact in both the Islamic world and the Latin West, but in neither culture was his thought accepted without resistance. In the Muslim East, the assimilation of his thought was opposed by the *ulama* (religious scholars), especially Asharite theologians, who maintained that apparent cause-effect relationships were illusions, and then virtually brought to a halt by the genius and arguments of al-Ghazali. In the Latin West, the Condemnations of 1270 and 1277 served to slow but not stop the assimilation of Aristotle into the fields of philosophy, theology, and natural science.

Abu Hamid Muhammad al-Ghazali (Latin, Al-gazel, 1058–1111) was an Islamic lawyer and a speculative theologian (*mutakallim*) trained in the Asharite school of theology (though critical of it) and, after a spiritual crisis, was perhaps most well known as a *sufi* mystic who legiti-

mized Sufism among Sunni Muslims. He has been called the “Proof of Islam” due to his many works in defense of Sunni Islam and is well known for his opposition to the use of philosophy in Islamic theology, specifically the Neoplatonized Aristotelianism of Ibn Sina (Latin, Avicenna). Nevertheless, his attitude toward philosophy was more complicated than this brief description suggests. For example, he wrote the *Standard for Knowledge* not only to explain Avicennan logic but also to encourage its use among theologians, whose logic, ontological arguments (ontology being the study of reality and the nature of being), and criticism of Islamic-Aristotelian philosophers were less sophisticated than those of the philosophers whom they attacked. Moreover, believing the Aristotelian logic of the philosophers to be superior, he criticized them for not always adhering to it. Also, to prepare for writing his masterpiece, the *Incoherence of the Philosophers*, he wrote a summary work entitled *The Aims of the Philosophers*, which summarized Islamic philosophical thought, especially that of Ibn Sina. Because this work was subsequently translated in the medieval Latin West, but without its explanatory passages, and because the *Incoherence* was not translated until the early Renaissance, much of the medieval West mistook al-Ghazali for an Avicennan philosopher!

Nevertheless, *The Incoherence of the Philosophers* (*Tabafut al-falasifa*, ca. 1091–1095), known to the Italian Renaissance as *Destructio philosophorum*, struck a serious blow to the study and use of philosophy in Islam, particularly in the Islamic East. So seriously was it taken that in Spain, Ibn Rushd (Latin, Averroes, d. 1198) felt the need to respond to al-Ghazali's attack point by point in his *On the Incoherence of the Incoherence* (*Tabafut al-Tabafut*, known to the Renaissance West as the *Destructio destructionis*), even though al-Ghazali's attack was directed primarily against Ibn Sina, and Ibn Rushd was no follower of Ibn Sina himself. It should be noted, however, that the use of philosophy did not completely cease in the Islamic East and indeed continued in the Platonic school of illuminationism of the Iranian theologian al-Suhrawardhi (1154–1191). But he was executed in 1191 on the orders of Salah ad-Din (Saladin), ostensibly for his religious views.

Initially, the writings of Aristotle were not wholeheartedly accepted in the Latin West either, particularly at the University of Paris where assimilation was slow and not without resistance. By 1255, however, students in the Arts Faculty of Paris were required to hear lectures on all of his available works. Even so not all was well, as there were philosophers in the Arts Faculty, usually termed “Latin Averroists,” such as Siger of Brabant and Boethius of Dacia, who wished to study Aristotle on his own terms without reference to theology or revelation. Nevertheless, they touched on theological issues such as the eternity of the world, much to the chagrin of the theologians. As a result, in 1270, 13 non-Christian propositions were condemned, including the doctrine of the Double Truth, that one can hold contradictory propositions, one true in philosophy, the other in theology, each true in its own realm (the idea being that some proposition or other of Aristotelian philosophy or science would be true if Scripture did not teach otherwise). Actually, no medieval Latin philosopher held this position, but some seem to have come close, such as Siger of Brabant.

In 1277 the archbishop of Paris, Etienne Tempier, at the request of Pope John XXI (the well-known logician Peter of Spain), condemned either 219 or (as now thought) 220 propositions. Most were non-Christian, and many were drawn from Aristotle, although some dealt with courtly love, magic, and necromancy. Similar condemnations at Oxford soon followed. Some scholars argue that the condemnations were specifically aimed at the Dominican theologian Thomas Aquinas, but because only about 13 of the propositions were positions held by Thomas, it is a theory difficult to defend.

The results of the condemnations confined use of Aristotle to certain areas, that is, as a philosophical rather than a theological authority, and limited theology as a science, making it more speculative, with discussion now focused largely on God’s absolute and ordained powers, very much like the concerns of Islamic Asharite theologians. Although the use of Aristotelian thought in theology was now more precisely delineated and confined, ironically those who used him were more strictly Aristotelian than those before, the greatest example being Thomas Aquinas. Never-

➤ AL-GHAZALI ON CAUSE AND EFFECT

In *The Incoherence of the Philosophers*, al-Ghazali addressed the issue of the necessity of apparent cause-effect relationships in nature. Does nature operate according to laws that are independent of a Divine Power?

“The connection between what is customarily believed to be a cause and what is believed to be an effect is not necessary, according to our opinion; but each of the two [namely, cause and effect] is independent of the other. The affirmation of one does not imply the affirmation of the other, nor does the denial of one imply the denial of the other; the existence of one does not necessitate the existence of the other, nor does the non-existence of one necessitate the non-existence of the other. [Take] for example: quenching thirst and drinking, satisfying hunger and eating, burning and contact with fire . . . and so forth for all the things which are observed to be connected in medicine, astronomy, the arts, and the crafts—indeed the connection of these occurs because the decree of God preceded their being created in this sequence, not because the existence [of this connection] is necessary in itself, not receptive of separation. On the contrary, it is within the power [of God] to create satisfying hunger without eating, . . . and so forth for all connections. The philosophers, however, deny the possibility of this and affirm its impossibility.”

theless, the boundaries of natural theology decreased after 1277, as the limits of “faith” and “reason” were more strictly delineated. In addition, scientific development, especially in such areas as optical physics and motion, now increased, as Aristotle had less of a hold on natural philosophy (the study of the physical universe). Thus, the Condemnations of 1277 have been

► THE REHABILITATION OF THOMAS AQUINAS

The death of Thomas Aquinas in 1274 precluded any possibility of Thomas defending himself from the charge that he held a number of the propositions condemned in 1277. The Dominicans, however, took up his defense, which culminated in his canonization as a saint in 1323. The order defended Thomas's teaching in 1279 against a work by the Franciscan William de la Mare entitled *Correctorium* (*The Correctory*), which the Dominicans referred to as the *The Corruption* (*Corruptorium*), and replies to the Franciscan rejoinder were known as *The Corrections of the Corruption* (*Correctoria corruptorii*). The Dominicans tolerated no opposition to Thomas's teaching within the order, and the 1279 General Chapter held at Paris prohibited any attack on Thomas's thought by any Dominican friar. Further, in 1286 the order stipulated that all Dominicans must promote and defend Thomas's teaching. This was reiterated in 1313 and again in 1314 due to the fact that Friar Durandus of Saint-Pourçain openly held positions contrary to those of Aquinas. The order also stipulated that all young Dominican friars who desired to attend the order's school in Paris (and ultimately the University of Paris) had to first complete three years' study of Thomas's works.

The process of Thomas's canonization began in 1317 and was completed on July 18, 1323, under Pope John XXII (r. 1316–1334). Thomas's rehabilitation became complete on February 14, 1325, when the bishop of Paris, Étienne Bourret, re-

Thomas Aquinas, thirteenth-century Italian theologian and saint, fresco by Fra Angelico. (Bettmann/Corbis)

moved the sentence of excommunication from the propositions condemned in 1277 that touched on Aquinas's teachings.

William of Ockham and the Nominalist Challenge

The Franciscan William of Ockham (ca. 1285–1347) was arguably the most significant thinker in the Latin West of the fourteenth century. Ockham has traditionally been called the founder of late medieval Nominalism, a school that (among other things) is traditionally thought to have held that universals (characteristics or qualities, such as humanity) are merely names (*nomines* in Latin) and do not exist apart from the mind or

apart from the particular things to which they give form. In fact, however, he held what is called the *intellectio-theory*: that universals exist primarily as concepts or acts of understanding in the mind and are qualities but are only secondarily related to the words that represent them. This was a position similar but not identical to that of Peter Abelard. As a result, some scholars prefer to call Ockham a conceptual realist or a mental act theorist. Interestingly, Ockham never referred to himself as a nominalist, nor did anyone until the late fifteenth century, and then the reference (in his defense) was to his logic, not to his position on the problem of universals. Moreover, recent research on the origins of Nominalism in the twelfth century calls into question whether it had anything to do with the status of universals at all. Indeed, Peter Abelard was referred to as the “Prince of the Nominalists,” yet he was not a nominalist regarding the status of universals. Nevertheless, there was a controversy regarding universals among medieval thinkers, even if the term “nominalist” was incorrectly applied to one of the positions by later scholars, as seems now to be the case.

Ockham is well known for the principle of parsimony, often called “Ockham’s razor,” one form of which is “Plurality is not to be posited without necessity” and that, in other forms, is sometimes interpreted to mean that the simplest answer is usually the correct one. Although this principle was commonly used by both ancient and medieval philosophers prior to Ockham, he seems to have used it to an extreme.

Ockham also emphasized the radical contingency of creation by emphasizing God’s power and freedom. While some scholars have argued that Ockham’s God can change the created order arbitrarily according to his absolute power, for Ockham there is only one power in God, viewed from two different perspectives (absolute and ordained power). God’s absolute power consists of all the possibilities open to God prior to creation but now no longer open to him due to his creation of the current order. Through creation, he has established a covenant with that order and thus freely binds himself to observe that order. God acts only according to his ordained power but not absolute power, and he will not arbitrarily change any aspect of the or-

➤ WILLIAM OF OCKHAM, “HERETICAL” FOE OF POPE JOHN XXII

The Franciscan minister general Michael of Cesena had been called to Avignon because of the crisis with the Franciscan Spirituals, who wanted to live the Franciscan *Rule* and *Testament* of Francis to the letter, particularly as they pertained to the issue of apostolic poverty. Michael asked Ockham, who was at Avignon undergoing his own examination for heresy (no formal censure was ever issued on any of his work), to examine the bulls of John XXII (r. 1316–1334) on Franciscan poverty, which declared heretical the idea that Christ and the Apostles owned nothing, thereby appearing to contradict what Pope Nicholas III had declared was Gospel teaching in 1279. The pope further transferred all property used by the order from papal ownership to the ownership of the order, thus abrogating the conception of poverty of even the more liberal Conventuals, the mainstream of the Friars Minor, who had accepted a modification of Francis’s strict definition of apostolic poverty by living in convents that they technically did not own. Based on Scripture, Church tradition, and previous papal bulls, Ockham, who up to this point had not been involved in the poverty controversy, determined that John XXII had fallen into heresy on both this and another issue. In 1328 Michael and Ockham fled to the court of Louis IV (r. 1328–1365) of Bavaria and were excommunicated for leaving Avignon without papal permission. A now-radicalized Ockham spent the period from 1328 to 1347 writing antipapal works concerning papal and imperial authority, papal infallibility and heresy, and the proper relationship between church and state. He died in Munich in 1347.

—Kimberly Georgedes

der he has created (i.e., ordained). Moreover, by his own nature God was not obligated in any way to, for example, create the cosmos in this particular way according to these particular physical, moral, and soteriological (i.e., those pertaining to salvation) laws. He could have chosen to create another order in another way. Nevertheless, using this dialectical analysis of God’s powers was a convenient way for theologians such as Ockham to discuss counterfactual possibilities, such as whether God could cause the past not to

have happened or whether he could have created a better world. The use of this distinction for such discussions became important after the Condemnations of 1277 and would aid in the rise of science in the West.

Ockham also greatly stressed humankind's freedom of will and the "liberty of indifference," in which one is not necessitated to choose an object or act simply because the intellect presents it as good to the will, nor is one bound to choose any object or act at all. There are still differences of opinion about many aspects of Ockham's thought, including his epistemology (the nature and extent of human knowledge) and ethical theory. While there is clearly an aspect of Divine Command to Ockham's ethical theory (that is, acts are right or wrong simply because God says so, through revelation), nevertheless there is also a strong foundation of natural law and right reason both in Ockham's ethics and political thought.

■ Introduction: The Place of the Human in the Cosmos

Humans seek to define their place in the universe through both religion and secular studies. Prior to modern times, religion was the primary means used to explain humanity's position in the cosmos and to make clear the purpose of human life. Notwithstanding the primacy of religion in this regard, a number of thinkers—philosophers, scientists, jurists, writers, and scholars of the humanistic arts—also offered at least tentative answers to this basic human quest during this half millennium.

In China, philosophy was secular, rational and, for the most part, eminently practical, with most philosophers concentrating on ethics and political philosophy. Indeed, both were intimately connected. Virtue merited an imperial dynasty the Mandate of Heaven (or the right to rule that

was bestowed by Heaven, a cosmic moral force and not a deity). Improper behavior was punished by disasters of every sort, including natural catastrophes such as floods, and the consequent loss of the Mandate of Heaven. Even the thirteenth-century Neo-Confucians, who introduced metaphysical elements into what had been for more than 1,500 years a down-to-earth Confucianism, emphasized moral behavior above all else.

Although several Chinese dynasties during this age promoted various forms of Buddhist devotion, namely the Yuan and Ming dynasties, religion on a family level in China tended to be personal and syncretic, with most families practicing a mixture of Daoist, Buddhist, Confucian, and folk-religious rituals. On the state level it was largely Confucian, with the emperor performing

rituals that ensured the favor of Heaven and prosperity for the Middle Kingdom.

The lines between theology and philosophy were blurred at best within the Abrahamic tradition to the point that Jewish, Christian, and Muslim philosophers were, by and large, primarily theologians, although there were exceptions to that rule. The same could be said for the dizzying variety of Hindu traditions in which the countless and ever-expanding sacred texts of India defined life and human behavior. Within Buddhism, which had become a pan-East Asian phenomenon well before 1000 CE, Theravada and many Chan, or Zen, savants were able to separate the search for Enlightenment from issues relating to the existence of the gods. Thinkers within the many varieties of Mahayana Buddhism, however, which predominated throughout most of East Asia, tied their search for answers to a multiplicity of divine Buddhas and bodhisattvas.

History and law also offered answers, or at least partial answers, to the question of humanity's place in the cosmos. Within many, but certainly not all, cultures these two areas were likewise tied to religion.

An understanding of the course of history within the traditions of such Mesoamerican and South American peoples as the Maya, the Aztecs, and the Incas proceeded from cosmological principles deeply rooted in their respective religions. In nonliterate societies across the globe, history consisted of oral traditions that placed a people squarely into the context of Creation and the ways of deities and spirits, thereby providing a pattern for proper behavior.

Within the monotheistic Abrahamic tradition, human history was primarily a subset of Sacred History, inasmuch as the actions of humans were interpreted within the context of the eternal Divine Plan. Thus, humans either functioned as agents of God or as agents of Evil and were judged accordingly. There were, however, significant exceptions to this rule. In Latin Christian Europe by the thirteenth century a number of persons were writing purely secular histories, and the numbers of such historians multiplied in the centuries that followed. The later crusades, the city-states of Italy, and the emerging nations of France and England proved exceptionally fer-

tile breeding grounds for secular historiography (the writing of history) such as the *Chronicles* of Jean Froissart (ca. 1337–ca. 1405), which focused on chivalric deeds. But even Giovanni Villani (ca. 1280–1348), a banker-historian of Florence, a city that is often termed “the birthplace of the Renaissance,” could compose a sweeping history of his city that was based on the assumptions that the forces of Good and Evil are in constant struggle and that human events are driven by Divine Providence. On its part, Byzantium produced many secular histories and did so far earlier than the Latin West because the Byzantines had classical Greek historians as their models. Very much like Plutarch (46–120 CE), Michael Psellus (1017/1018–1096), one of Byzantium's greatest historians, focused on the human psyche as a driving force in history in his *Chronographia*, a history of the reigns of 14 emperors and empresses. Yet even though their histories were essentially secular in scope, most Byzantine historians spent many pages and much ink on chronicling religious disputes because of the intimate relationship between empire and church. Islam also produced a fair number of historians who wrote purely secular histories, the greatest being Ibn Khaldun (1332–1406). Although he was trained as both a theologian and an Islamic jurist, his *Kitab al-Ibar (Universal History)* and especially its *Muqaddimah (Prologue)* mark him as not only a secular historian who displayed a special interest in cultural dynamics but also as the progenitor of several social sciences, including economic theory, demography, and sociology.

Secular historiography was a venerable Chinese tradition stretching back at least to China's greatest historian Sima Qian (145 or 135–86 BCE), and within this tradition history was seen as a guide to proper behavior, especially on the part of emperors and their ministers. As already noted, virtuous behavior, which meant conformity to the values and ways of the Ancestors, ensured the favor of Heaven. It was in this vein that Song China's greatest historian, Sima Guang (1019–1086), composed his *Comprehensive Mirror as an Aid to Government*, a universal history of China that enjoyed imperial patronage and guidance.

As with historiography, Chinese law was eminently down-to-earth and practical. Judges were

expected, at least in theory, to be rational in their investigation of each case and application of the law. To the contrary, law in the Hindu tradition was *dharmā*, or sacred caste law, as articulated in such compendia as the *Laws of Manu*, which spelled out the rules governing behavior for castes and sub-castes (*jatis*). As such, these laws, although they included many contradictions, were considered timeless and a manifestation on earth of Brahman, or the Universal Soul.

Within the Abrahamic tradition, Jewish law was the sacred Torah, which had been given by God to Israel through Moses, and the Talmudic commentaries on it. Because Jews lacked a state of their own (except for the short-lived Khazar kingdom), the rabbis who administered this law did so within the confines of Jewish communi-

ties that were the subjects of non-Jewish polities. Islam, to the contrary, was both a religion and a state (actually many different states), and Sharia, its sacred law, which had been given by God to the Prophet and was interpreted by trained *qadis*, functioned in both spheres. Indeed, within the ideal Islamic community, there was no separation between religion and government. Within the Christian traditions of Latin Europe and Byzantium, there were church law (known as canon law in the West) and secular law, although there were significant overlaps. In both traditions, for example, heresy, or perverse religious belief, was an offense against the state as well as God and the Church and was punishable accordingly by the temporal authority.

In summary, despite some obvious parallels, attempts by humans to fix their place in the cosmos and to give meaning to their lives were as varied as the many cultures that flourished around the globe.

—Alfred J. Andrea

► THE QADI IBN BATTUTA

Abu Abdallah ibn Battuta (1304–1369) is better known for his remarkable journeys, which he undertook during 30 years of his life, than as a qadi, or religious judge. When Ibn Battuta arrived at the Delhi court in 1334, the sultan, Muhammad Tughlaq, was a ruler with a reputation for preferring to hire into his administration and judiciary foreign professionals from Islamic countries. Indeed, it was this policy, the reputed generosity of the sultan, and the famed splendors of the Delhi court that had attracted Ibn Battuta to travel to India. Although he had not yet established a reputation as a jurist, Ibn Battuta was nonetheless appointed as a Maliki qadi of Delhi. His *Rihla*, or account of his travels, provides very little information regarding his seven-year-long service as a qadi. His narrative, however, vividly depicts Islam in India and also provides impressions of the majesty of the Delhi sultanate court and the ambivalent character of Sultan Muhammad Tughlaq, who was very generous and an ardent lover of knowledge, especially of the Hanafi branch of sharia jurisprudence. At the same time, he was capricious and capable of taking extreme measures by applying the penalties of Sharia for minor offenses. Disturbed by such an environment, Ibn Battuta found a way to escape from the Delhi sultanate when the sultan asked him to leave for China as an ambassador.

—Husain Kassim

The Application of Sharia in India

Sharia, or Islamic religious law, was first introduced to India by Muhammad ibn Qasim, with the conquest of Sind in 712 and its incorporation into the Abbasid caliphate. Later Sharia was enforced in India as an administrative and judicial policy by the Delhi sultans of various dynasties from 1210 to 1526. Its authority was formally accepted throughout the Delhi sultanate period mainly to underscore their legitimacy to rule. Moreover, revenue from the poll tax (*jizya*) imposed on non-Muslim subjects was substantial. However, the policy of levying the poll tax varied from one sultan to another. Alauddin Khilji (r. 1294–1316), instead of levying a poll tax, introduced a policy of taxation on agricultural produce at the rate of 50 percent, the maximum allowed by Sharia. In addition, he levied a grazing tax (*charat*) and a tax on dwellings (*sakumatgarbi*) that were not sanctioned by Sharia. The pious Firuz Shah Tughluq (r. 1351–1388), on the other hand, abolished all taxes that were not sanctioned by Sharia, levying instead four permissible taxes: a land tax (*kbraj*), state-collected alms-giving of 2.5 percent (*zakat*), the poll tax, and one-fifth of booty (*kbums*). A fervent anti-

➤ IBN KHALDUN'S MEETING WITH TAMERLANE

It is often surprising for people to learn that Ibn Khaldun's *Muqaddimah* was written during a brief period of inactivity in the writer's life. Ibn Khaldun was many things in his long and distinguished career, from a political aide to a jurist and theologian. His many travels brought him to Cairo, where the Mamluk sultan Barquq (r. 1382–1399) appointed him *qadi al-qudat* (supreme judge). Although somewhat elderly, being in his late 60s, the *qadi* ended up in Mamluk-dominated Damascus during its conquest and sack in 1401 and was asked to join the forces that were sent out to meet Timur-i Leng (Tamerlane) in battle. After the defeat of the Mamluk defenders, Ibn Khaldun was forced to negotiate his own surrender.

In his autobiography, Ibn Khaldun dealt at length with his meetings with Tamerlane, providing us with great personal insight. He noted that Tamerlane seemed to be neither Sunni nor Shia and mentioned his leniency to those who capitulated. That is not to say that Ibn Khaldun was enamored with Tamerlane. He reserved his harshest language for the destruction of the Umayyad mosque in the city's heart and commented at length on the cruelty of Tamerlane in subsequent personal letters. But while Tamerlane might display cruelty at one moment, Ibn Khaldun also noted that he was always ready to play chess or debate complex theological and philosophical questions.

—Rasheed Hosein

Muslim historians, such as al-Tabari and Masudi, and commented upon them (and the errors they made) in the *Muqaddimah* of his *Kitab al-Ibar* (*Universal History*). With his training, Ibn Khaldun proved useful in many governmental capacities.

The North Africa of Ibn Khaldun's time was unstable, with new ruling dynasties replacing older ones every few years. As a result, he moved from court to court as political fortunes dictated. His journeys took him from Tunis to Fez (then the center of learning in Muslim West Africa) and eventually to his ancestral home of Seville in Christian Spain. After brief periods of service to various rulers of the region, he retired for a period of four years to the castle of Ibn Salama (near Oran), where he began his composi-

tion of the *Muqaddimah* and the *Kitab al-Ibar*. Once they were completed he moved back to Tunis, but eventually he grew disenchanted and left under the pretext of going on pilgrimage, or Hajj, to Mecca. His life in the eastern part of the Islamic world was no less tumultuous. He witnessed the sacking of Damascus by Tamerlane and attended the purging of corrupt *qadis* (judges) in Cairo. Ibn Khaldun died in Cairo on the 26th of Ramadan (March 16, 1406) at the age of 74.

In terms of its structure, the *Muqaddimah* translates into roughly six chapters of varying lengths. The first chapter deals with civilization in general, with specific references to Arab and North African models. In six prefatory discussions, Ibn Khaldun looked at why some contemporary societies were more advanced than others. This all amounted to a concerted effort to describe the world in scientific terms.

Overall, Ibn Khaldun's novel approaches to the nomad-sedentary dynamic and the rise of dynasties are two of his greatest contributions to the historical record. According to him, both activities are the product of *asabiyyah* (solidarity). It is something inherent within humanity and varies in intensity depending on whether one is nomadic or settled. According to Ibn Khaldun, nomadic groups have a higher *asabiyyah* than those that live in cities because the nomad lives free in nature, while the city dweller lives under the law. The law forcibly subverts the nature of the man, making him weak. Therefore, when conflict occurs, the group with the higher *asabiyyah* wins. This replicates the cycles of history witnessed by Ibn Khaldun himself. However, once the nomads are brought into contact with the settled peoples and begin to rule over them, they in turn settle. Their solidarity weakens, opening the door for conquest by a more unified group. Thus, a chain is formed. Humanity needs *asabiyyah* to survive in the wild; it also compels people to establish rule over those who are weaker, and it makes possible the formation of laws. Thus, the rise and fall of civilization is a self-sustaining enterprise, one that is by nature a necessary expression of *asabiyyah*.

Within the larger dynamics of the rise and fall of civilization there occurs the smaller cycle of the rise and fall of dynasties. Ibn Khaldun placed the life cycle of any given dynasty at four

generations. When a group becomes dissatisfied with the state of affairs, it is compelled to overthrow those in power. Since this works in accord with the will of the people, the founder is almost always held in high esteem. With the second generation still connected strongly to the *asabiyyah* that created the dynasty, we begin to see discontent as the ruler begins to promote his own interests. Totally removed from the *asabiyyah* that established the dynasty, the third-generation ruler forsakes the law in favor of policies to satisfy his vices and becomes alienated. Ancestral prestige is destroyed by the excess and vice of the fourth and last generation. However, if there is no one in possession of *asabiyyah*, then the dynasty will gain a brief reprieve until one group rises to challenge it. Ibn Khaldun places the time frame at 120 years. It is important to note that these conclusions were born of his historical observations, marking Ibn Khaldun as a major social historian.

Zhu Xi and the Neo-Confucian Reshaping of Chinese Thought

Zhu Xi (1130–1200) is the most influential Chinese thinker of the past 800 years. His reinterpretation of the Confucian classics dominated education and official ideology from the Yuan dynasty (1279–1368) until the abolition of the examination system in 1905. Zhu's position in laying the foundations of Neo-Confucian orthodoxy has often been compared with that of Thomas Aquinas (ca. 1224–1274) in the Western Christian tradition.

Zhu Xi must be regarded as a major world philosopher and religious thinker because he completed the task of reconstructing Confucian-

➤ MASTER ZHU ON MORAL PERFECTION AND BOOK LEARNING

Long before Zhu Xi's philosophy was canonized as official state orthodoxy, his students wrote down and collected their master's conversations, which were ultimately published in book form in 1270. The following quotation is an example of his philosophy:

"Book learning is of secondary importance. It would seem that moral principle is originally complete in man; the reason he must engage in book learning is that he hasn't experienced much. . . . Now in book learning we must simply apprehend the many manifestations of moral principle. Once we understand them, we'll find that all of them were complete in us from the very beginning, not added to us from the outside."

ism into a complete system of cosmology, metaphysics, ethics, and spiritual practice fully capable of competing with Buddhism and Daoism. The latter traditions had dominated Chinese spiritual life for over a millennium, from the end of the Han (202 BCE–220 CE) into the Song (960–1279) dynasties. The radical shift in Chinese elite culture represented by Neo-Confucianism was closely related to the decline of the aristocracy following the fall of the Tang dynasty (618–907) and its replacement in the Song by a meritocratic system of officeholding based on the examination system, which required years of study of the Confucian classics.

Zhu Xi spent 40 years of his life in educational work and served as an official for less than 10 years, a fact that clearly affected the nature of his teachings. In his disputations with other Confucian scholars, he emphasized the importance of broad learning, observation, and systematic intellectual inquiry over the contemplative pursuit of virtue, which he thought was too close to

Buddhism and Daoism. Nevertheless, he still believed that the goal of learning was not simply the accumulation of knowledge and literary skills but rather the achievement of a penetrating insight into the fundamental nature of things that would transform a person's character and physical nature. He also emphasized the importance of quiet sitting (meditation) as a balance to engagement in study and work. And the most important aspect of knowledge was the understanding of moral principles, an understanding that requires one to put one's knowledge into practice in both personal relationships and government service.

It was through his emphasis on the reality and rational accessibility of unchanging metaphysical principles that create order in both the natural and human worlds as well as his insistence on the importance of objective knowledge of the world that Zhu completed the work of his predecessors in revitalizing Confucianism. These principles were called *li*, a character that as a noun refers to regular patterns or orderliness and as a verb means to put things in order. Principles—particularly the fundamental moral principles that are the basis of social order and harmony—were also referred to by the word “Dao” (Way). All the principles of individual things and affairs, Zhu Xi taught, were particular manifestations of a single principle, for which he used the term “Supreme Ultimate” (*Taiji*). Individual things or human beings are also able to fully manifest the *Taiji* in themselves, and the *Taiji* is the foundation of their existence. The differences between things and persons are due to their different endowments of *qi* (material force).

All things and affairs are governed by definite principles and norms and necessary laws, and if people are in accord with these principles and laws, they can manage affairs easily with no need to resort to artificial effort. Accordingly, an understanding of principle must come first, and action follows. *Li*, moreover, is present within human beings as their nature (*xing*), the virtuous nature mandated by Heaven as opposed to the physical nature, the mixture of *li* and *qi* that gives rise to human desires. Historically, Zhu believed that the world was ruled in accord with heavenly principle by sage rulers in the ancient period of the Three Dynasties (Xia, Shang, and

Zhou) but that subsequently human desires ran amuck, and rulers began to rule by force and despotism instead of the power of virtue. It was Zhu Xi's commentaries that established the Four Books—*The Great Learning*, *The Analects*, *The Teachings of Master Mencius*, and *The Doctrine of the Mean*—as the core object of study for China's civil service examinations from the fourteenth century to the early twentieth century.

Zhu Xi's Neo-Confucianism traveled to Korea and found a home in Japan as well. Early in the seventeenth century, Ieyasu, the first Tokugawa shogun, adopted Neo-Confucian thought as official ideology to buttress his reorganization of Japanese society.

Neo-Confucianism in Japan and Korea

Neo-Confucian scholarship and philosophy arrived in both Korea and Japan shortly after its systemization in China during the Song dynasty (960–1279) and became a crucial part of the cultures of both Korea and Japan, although its impact was more pronounced in the former rather than the latter before 1500.

After the fall of the Song dynasty, Korean representatives traveled to China in order to establish relations with the new Yuan dynasty (1279–1368). It was during these visits that Korean scholars became acquainted with Neo-Confucianism. As the Yuan dynasty declined, so too did the fortunes of the Koryo dynasty (918–1392) in Korea. Inspired by the moral philosophy of Neo-Confucianism, Korean scholars called for reform. These efforts, however, could not save the dynasty, and it was overthrown in 1392. The founder of the Joseon dynasty (1392–1910), Yi Seong-gye (1335–1408, r. 1392–1398), brought some of these reformers into his government. With

their help, he established a new state founded on Neo-Confucianism.

Buddhism was an important part of the history of Neo-Confucianism in both Japan and Korea. There had always been an affinity between the two traditions even in Song China. Chinese Chan (known as Zen in Japan) monks and priests embraced Neo-Confucianism as fundamentally the same as Chan, while Neo-Confucian scholar officials denied any similarity between the two. This ambivalent relationship between Buddhism and Neo-Confucianism carried over into Korea and Japan. Buddhist monks who studied Neo-Confucianism were mostly Zen, especially those of the Gozan temples in and around Kyoto. In Korea, the Neo-Confucians who helped create the Joseon state began a persecution campaign against Buddhism, which they linked to the moral degeneracy of the previous dynasty. Through the connection in Neo-Confucianism between moral teachings and political theory, they believed that they could avoid the fate of the Koryo. In a similar way, Neo-Confucianism grew in influence during the Southern Song dynasty (1127–1279) in China following the capture of the north by the Jurchen in 1127. The most influential of China's Neo-Confucians, Zhu Xi (1130–1200), asserted that China's main goals were to shore up its moral foundations and to recapture the north. According to traditional Chinese thought, proper moral behavior was the foundation of a stable society, and immoral behavior invited inevitable social and political disaster.

The separation of Buddhism and Neo-Confucianism also occurred in Japan but not until the middle of the sixteenth century. Prior to this time, the monks who studied Neo-Confucianism were mostly Zen Buddhists, especially of the Gozan temples of Kyoto. Since they were primarily Zen Buddhists, the similarities between the two traditions were especially appealing to them. For example, the Zen notion of enlightenment (*satori*) resonated with the Neo-Confucian concept of original goodness (*bonzen no sei*). Other than Confucius (ca. 551–ca. 479 BCE), the Neo-Confucians admired the philosopher Mencius (372–289 BCE), and they placed special emphasis on his idea of original goodness. According to this notion, one was born in a state of near moral

➤ JOSEON ENDORSEMENT OF CONFUCIANISM

The following passage is from Jeong Dojeon (1342–1398), one of the chief Neo-Confucian advisers to Yi Seong-gye (1335–1408), the founder of the Joseon dynasty. In it, he dismisses both Buddhism and Daoism as harmful to the Korean state.

“Through the discussion of the following poems this essay will mainly argue for the correctness of the principle of righteousness of Confucianism and, by reasoning against Buddha and Lao Tzu (Laozi), it tries to make the reader aware of their falseness. . . . If one keeps righteousness in his heart and nourishes it, he will eliminate the shroud of material desires, all will become lucid. . . . If one concentrates his righteousness while nourishing and expanding his material force, it will become the greatest and stoutest power, strong and moving . . . filling up all between heaven and earth. The beginning and the end will join together and the internal and external will be cultivated alternately. This is why the learning of the Confucians is correct and is not like the biased learning of the Buddhists and the Taoists (Daoists).”

perfection; during the course of one's life, this moral state became corrupted with the accumulation of selfish desires. Thus, in order to return to that state of original goodness, one had to eliminate those desires. In Buddhism, the elimination of desires is also a central goal for its adherents; thus, as one worked to restore one's original goodness, one was at the same time moving toward enlightenment. Building on the ideas of Mencius, the Neo-Confucians outlined ways in which people could morally rectify themselves. Specifically, they devoted themselves to the study of the Confucian canon (the Four Books and the Five Classics). Moreover, certain rigorous practices such as quiet sitting (which was similar to Zen meditation) were crucial as well.

Western Ethical Philosophy from Abelard to the Early Humanists

Peter Abelard (1079–1142) started a process that altered the study of ethics in the Latin West by raising questions about the authorities on which the scholastics relied and by suggesting a moral standard that was grounded in general revelation (God revealed through nature) rather than special revelation (God revealed through the prophets and supernatural intervention). This focus on human ethical actions that emphasizes the primacy of reason over religious authority is generally known as humanism.

Abelard stands out as having one of the most turbulent professional and personal lives among the scholars of Europe's Middle Ages. His relationship with Heloise is well known. His ethical theory is in part an explanation of his behavior toward her, a rejection of Realism (the theory that universals are real in themselves, as was taught by Plato), and a return to Greek philosophy's study of the good and human nature. In rejecting Realism, Abelard opened the door for other humanists to argue for Nominalism (the view that there are no universals) or perhaps Conceptual Realism (the view that universals exist only in the mind) and the divine command theory (the morality of an act depends solely on whether God commands or prohibits it).

During his time as a student in Paris, Abelard was taught by William of Champeaux, who was a Realist. In opposition to William's Realism, Abelard argued for what has come to be called Conceptualism, which states that universals are concepts in the mind, ultimately the mind of God. Like Nominalism, this view maintains that universals are not real in themselves, but unlike Nominalism it does not deny the existence of universals altogether.

It was during his time in Paris that Abelard first met Heloise and worked as her tutor. This led to a romantic relationship that culminated in a secret marriage that Heloise denied out of fear that being married would harm Abelard's career. In anger at this situation, Heloise's uncle paid ruffians to castrate Abelard. Thus shamed, Abelard and Heloise both spent the rest of their lives under monastic vows, with letters from Heloise displaying her continued devotion to Abelard, while his display a distant reserve. His explanation of these events, in *The Story of My Misfortunes* (*Historia calamitatum*), is a demonstration of his ethical theory in that although he recounts behavior that was not good, he argues that his intentions were good, and so what happened to him was misfortune rather than deserved consequences.

The development of Abelard's humanist philosophy worked through these personality and behavioral issues. His questioning of William's authority and struggle against the monastic ideal of the day were expressions of Abelard's philosophy. Perhaps Abelard's most significant influence is in his work *Sic et Non* (*Yes and No*) in which he used a dialectical framework to display answers from the Bible and Church fathers to various weighty theological questions. The answers are apparently contradictory. Abelard made suggestions about how the contradictions might be reconciled, but this aid did not appear in the work itself. The application of dialectic to theology influenced later thinkers, such as Peter Lombard. However, Abelard's method raised questions about the authority of the Church fathers. Even if the contradictions are only apparent, there must be some authority in addition to the Church fathers that allows humans to understand what is being said and to work out the apparent contradictions into a coherent system. This reliance on reason led to the appearance of conflict between reason and theology that would be an important part of later humanism.

Abelard expressed his ethical theory most clearly in *Know Thyself*. The title is an indication of his reliance on Greek philosophy. In itself this was not unique for his time, but coupled with the questioning of authority implicit in *Sic et Non*, Abelard's direction was to ask what can

be known from general revelation about the good and God.

Abelard's answer about what makes an action good was that this depends on intentions. Good intentions behind a harmful action are better than evil intentions behind a beneficial action. Abelard even extended this to those who crucified Christ, saying that since they believed that what they were doing was good, their action was not as bad as someone who intended evil. Although in some ways this definition of "good" raises problems about the objective distinction between good and evil, Abelard seems to have grounded evil in a contempt for God shown through an intention to break God's law. Yet as Alistair MacIntyre points out, Abelard provided a standard for judging what is good and evil that is not necessarily tied to a Christian or theistic outlook.

Abelard's legacy in the academy, and one of the reasons that humanism can be traced to him, is that he helped develop the study of subjects that were not within an earlier theological-philosophical framework and raised important questions about what humans can know apart from special revelation.

Benefiting from Abelard's attack on Realism, William of Ockham (ca. 1285–1349) also contributed to thinking about ethics. Ockham did not believe that there are universals regarding "the good" that exist independent of the mind. Consequently, he developed what is called the divine command theory, which is defined above. This action of God in determining what is good is not grounded in the nature of things (which implies universals) but is solely dependent on the will of God. As such, Ockham was also a voluntarist, rooting the good in the divine will and independent of the human intellect or emotions (or intentions). Francesco Petrarca (1304–1374), also known as Petrarch, has been given the title "father of humanism" in the sense that he ushered in Renaissance humanism. Whereas Abelard helped open the field of study to new subjects, Petrarch contributed to numerous fields, including philosophy and literature, in a way that others before him had not. He argued that God gave humans a mind and that it should be developed to the fullest of its abilities. This led him to

➤ SIMONY IN WESTERN THOUGHT

Simony is the practice of buying or selling a church office or anything that is sacred. It is named after Simon Magus who, as recorded in the book of Acts, witnessed the Apostles performing miracles and asked if he could buy such power. Although it is common for one's initial intuition to be against the practice of simony, its origins are not merely in an avaricious appetite for power and wealth but rather in the relationship between the civil and ecclesiastical authorities.

In the European Middle Ages, popes such as Gregory VII (r. 1073–1085) and Innocent III (r. 1198–1216) worked to reform the Church and cleanse it of simony, which in their minds corrupted ecclesiastical offices by handing over the sacred to the secular. However, the practice of civil authorities appointing bishops and abbots was related to the fact that these church officials controlled large tracts of land and therefore had extensive civil authority. Consequently, kings and other lords wished to ensure that whoever occupied a bishopric or the abbatial office of a monastery would be favorable to their policies. Thus, even when the actual practice of simony was more consistently prosecuted, kings and lords continued to insist on having some influence on who would be appointed to these positions.

One suggestion about how to end civil influence on who holds a church office was that these offices should not have vast possessions of land and wealth. Indeed, it was argued that this was contrary to the spirit of Christianity, and persons such as Francis of Assisi (1181/1182–1226) took vows of absolute poverty in the belief that this was how a Christian should live. This ideal, however, was never widely adopted, and simony remained a fact of ecclesiastical life well past 1500.

—Owen Anderson

look both at earlier Christian scholars, such as Augustine, but also at non-Christians, such as Cicero. Petrarch promoted the Renaissance ideal that Roman and Greek scholars had fully developed some of their human qualities but needed special revelation and grace to complete their humanity.

Petrarch's ethical philosophy expressed a kind of moral dilemmas approach. He wrestled with questions about whether the public political life or the reclusive contemplative life is best. As was the case with Dante (ca. 1265–1321), Petrarch idealized a woman he hardly knew, and this came to expression in his poetry. He contributed to a more intuitive approach to the good life, and this in turn led humanism to generally adopt a skeptical attitude about knowing the good as a universal and instead to focus on individual cases of what it means to flourish.

The final humanist to be considered for this era, who lived as a transition between the Renaissance and Reformation, was Desiderius Erasmus (1466?–1536). His ethical theory combined the curiosity and exploration of humanist studies within the confines of received tradition. His breadth of learning places him at the forefront of the thinkers of his day. He was involved in both humanist studies and in theology. Martin Luther hoped that Erasmus would see the value in the Lutheran Reformation, and Erasmus did concede that many reforms were needed in the Church, but ultimately he did not believe that a break with the Roman Church was ethical. He upheld Roman Catholic doctrines such as transubstantiation (the substance of bread and wine was transformed into the substance of Jesus's body and blood at the moment of priestly consecration) and the seven sacraments. Consequently, this era of humanism ends without having demonstrated how knowledge of the good from general revelation is possible. The subsequent history of humanism will largely consist in skeptical critiques of Christian knowledge claims, culminating in David Hume (1711–1776).

The West's Rediscovery of Plato—The Early Years

With the revival of the study of classical Greek in Quattrocento (1400s) Italy, a succession of scholars began to translate Plato's dialogues into Latin, a process that culminated in the printing of Marsilio Ficino's edition of the entire corpus in 1484. But in the hands of mid-fifteenth-century scholars, what emerged was a systematized and Christianized Plato. This was a conception of Plato that built upon the Neoplatonic tradition of Byzantium, which gave a new dignity to humanity and had the potential to reform the cultural and spiritual life of Latin Christendom.

It was the humanists of northern Italy who first became interested in the Platonic dialogues. Humanists loathed what they saw as the obscurantism of medieval scholasticism, with its supposed linguistic barbarisms, convoluted theology, and unhealthy fixation with Aristotle. Conversely, Plato was not just renowned as a master of linguistic eloquence; he was also reputed to be a better philosopher than Aristotle. Consequently, when the Italian humanists first looked to Plato, they did so hoping to find not just a powerful philosophical alternative to medieval Aristotelianism but a potential champion of humanist values as well.

This predisposition profoundly colored the approach of Leonardo Bruni when he began to translate Plato's dialogues in 1405. Bruni found it reassuring that Plato had a notion of creation *ex nihilo* (out of nothing), the immortality of the soul, and an afterlife. More worrying though was Plato's disparaging comments about rhetoric, an art central to the humanist program. Worse, Plato had little sympathy for the idea of the active citizen, which to a civic humanist of Bruni's ilk was deeply distressing. Worse still, Plato seemed to endorse some ideas that were flagrantly immoral to a fifteenth-century Christian. Plato argued, for instance, for all wives to be held in common, and he endorsed both homosexuality and pederasty. Initially Bruni dealt with these unsettling discoveries simply by omitting them from his Latin translations, but by 1429 Bruni had had enough of Plato and wrote a life of Aristotle instead.

Yet despite this failure to annex Plato to humanism, the Platonic corpus was slowly integrated into Latin thought under the influence of a succession of Byzantine scholars. In the Greek world, Neoplatonism had never died out. A philosophical school that had flourished in the third century CE, it highlighted the various strands of Plato's metaphysical thought, reworking them into a single coherent system. It was this incarnation of Platonism that fed the theology of the early Christian Church. Indeed, St. Augustine had gone so far as to describe Platonists as those pagans who had come closest to discovering the truths of Christian revelation by rational means alone. Western scholars got a renewed taste of this thoroughly different Platonism at the Council of Florence in 1438. There a Byzantine Neoplatonist named Gemistus Pletho gave a lecture on the differences between Plato and Aristotle. In the years following Pletho's lecture, Bessarion, a Byzantine monk turned Catholic cardinal, provided the West with a complete Neoplatonic interpretation of the Platonic corpus, showing how Plato's thought ought to be construed as a systematic theology wholly in accord with the truths of Christianity.

While Bessarion's work was very influential, it was Ficino who completed the assimilation of Plato. Cosimo de' Medici, patriarch of Florence's leading family, provided Ficino with Greek texts of all 36 of Plato's dialogues in 1462, commissioning him to render them into Latin. To Ficino, reading the corpus through the lens of Neoplatonism, the proximity of Plato's thought to Christian revelation suggested that Plato was no ordinary philosopher; he was the culmination of an ancient theology. Before the coming of Christ, Ficino argued, God had revealed his mysteries to a few inspired sages. Chief among these were Moses and the prophets of the Old Testament, but also included were Plato and a number of other pagan luminaries, such as Hermes Trismegistus. To Ficino, Platonism was an ancient form of wisdom that had been given to the Greeks to prepare them for the coming of Christ and thus stood in the same relationship as Moses did to the Israelites. Consequently, Platonism was an ideal tool for the reformation of the church. While Aristotelianism had led only to strife and

➤ LORENZO THE MAGNIFICENT

Lorenzo de' Medici, called "Lorenzo the Magnificent," was a brilliant fifteenth-century Italian art patron, as well as the *de facto* ruler of Florence. (Library of Congress)

In his *History of Florence*, the great Florentine historiographer Francesco Guicciardini described Lorenzo de' Medici, the Magnificent (1449–1492), as a tyrant but noted that "if Florence was to have a tyrant she could never have found a better or more delightful one." To be sure, for 22 years, from 1469 until 1492, Lorenzo dominated the Florentine state. But while Lorenzo was a tyrant, he was a popular tyrant. The

key to his success was twofold. On one hand he was an astute, gifted politician and diplomat. Guicciardini went so far as to argue that the whole balance of power between the city-states of northern Italy was a product and function of Lorenzo's personality. But on the other hand, Lorenzo continued his grandfather Cosimo's policy of using Medici coinage to consolidate Florence's position as the most important cultural center in Europe and, by extension, securing the position of the Medici within the state. A poet and humanist of some distinction in his own right, Lorenzo also supported humanists such as Marsilio Ficino and Pico della Mirandola. Lorenzo established the Medici library, refounded the University of Pisa, transformed the University of Florence into the most important center for the study of Greek in the West, and in the final years of his life was patron to the young Michelangelo. For Guicciardini, Lorenzo's premature death signaled the end of a golden age and paved the way for the calamitous French invasion of Italy in 1494.

—Richard Raiswell

factionalism, the pure wisdom of the divine Plato was a pious philosophy that could lead the willing philosopher back to Christ.

Science and Technology

As previously noted in the introductory essay for the “Thought and Religion” theme, natural philosophy, or science, was intimately connected with philosophical thought and religion during the period 1000–1500, just as it had been for many centuries prior to this era and would be for at least a century after 1500. The same was not true for technology, which arguably saw greater and more significant developments than natural philosophy. Of all the areas of the world in which the most significant technological breakthroughs were made during this 500-year period, China was undoubtedly the leader, as it had been for the previous 500 years. To name but a few, such inventions included large textile machines that did the labor of many, blast furnaces for the production of steel, a hydraulic-powered astronomical clock, paddle-wheeled vessels and the fenestrated rudder and watertight compartments for these and other ships, gunpowder artillery, and new methods for large-scale iron casting. Many of these and other inventions undoubtedly made life easier and more rewarding for many Chinese, and they helped make China the most prosperous state in Afro-Eurasia and the engine that drove much of its economy. Yet neither individually nor collectively did they effect any fundamental changes in Chinese society. Several technological developments that sprang up in or were introduced to Western Europe prior to 1500, however—notably new forms of shipbuilding and naval navigation, printing by movable type, and firearms—proved, in the years immediately after 1500, to be revolutionary factors in the West. New ships, new modes of navigation, and firearms propelled Europeans along a path that would lead them by the early sixteenth century to dominance in those areas of the Americas that they had recently entered and, almost as significant, a place of importance for the first time along the coasts of Africa and South and East Asia. Printing would, as it had centuries earlier in China, prove to be a major stimulus for intellectual and religious activity in Europe. But printing in China (and Korea) was not a medium for significant social or intellectual change. In sixteenth-century Western Europe, however, it served as the means through which revolutionary religious and secular ideas were disseminated.

Although there is solid evidence that the technology of gunpowder and its military applications (as well as the crossbow and trebuchet) spread westward from China, as several entries for the “War and Diplomacy” theme demonstrate, there is no evidence that the use of the compass as a navigational device or the concept of printing through movable type made their way from the Far East to the Far West, although both were known in China and elsewhere in East Asia long before they appeared in Europe. They might have made the long trek westward, but it

is equally possible that they were invented independently in Europe. As is so often the case when we try to trace the possible spread of ideas that might have taken place in the distant past, we end up more with speculation than irrefutable fact.

The concept of printing through movable type quite possibly never made its way to Europe from Korea, which first developed the process and where it became the norm, or from China, which only experimented with movable type sporadically and eventually gave it up as ill-suited for the Chinese language's tens of thousands of characters. Traditional block printing was better suited to Chinese. That aside, there is abundant documentation for the westward spread of paper, probably a Chinese invention that went back at least to the early second century BCE. Without relatively cheap paper, mass printing would not have been possible in either China or Korea after 1000 or in Europe after 1450. Without paper, printing certainly would not have had the power to teach both the literate and illiterate alike in China and Korea the rules of proper behavior championed by the state. It certainly would also not have had the revolutionary impact on European thought and religion that it did, namely the spread of humanist scholarship and ideas and the rapid spread of the Protestant and Catholic Reformations.

Al-Jazari, who flourished during the late twelfth century and possibly into the first years of the thirteenth century, is illustrative of the genius and limitations of technology in Dar al-Islam.

The greater Islamic world did not lack for technological innovations during this age, but as in China and all other societies of Afro-Eurasia, except the Latin West, these devices were not factors for substantial social or intellectual change. Al-Jazari, who flourished during the late twelfth century and possibly into the first years of the thirteenth century, is illustrative of the

genius and limitations of technology in Dar al-Islam. He invented a number of engineering devices, including several hydrological wonders, but none of his inventions, which are carefully documented in his *The Book of Knowledge of Ingenious Mechanical Devices*, survived much beyond his death. Although several of them, especially hydraulic pumps, had undoubted practical application, most were novelties and devices for amusement.

There was another area in which the Islamic world exhibited antipathy to technological innovation. Whereas printing by movable type became a revolutionary tool in the European West by 1500, it failed to play a significant role within any Islamic society for about 400 years. Muslims were not ignorant of the technology. As early as 1493 Jewish refugees from Spain set up a press in Istanbul for the production of Bibles and similar religious literature. Yet, by and large, Muslims resisted adopting printing until the latter half of the nineteenth century. Apparently the major motive behind this resistance was that the mass production of cheap books ran counter to two embedded traditions. First, Islamic education, as promoted in its madrasas, was primarily oral. One recited from memory the suras of the Quran and other religious texts. Second, calligraphy, literally “beautiful writing,” was an Islamic art form that stretched back to the seventh century. The painfully careful pro-

duction of exquisite manuscript Qurans and other religious books was an act of piety, as well as a major industry.

In addition to beautiful, hand-written and hand-illustrated books, Muslim calligraphers also produced extraordinarily beautiful maps. Indeed, cartography and geography were areas in which Muslims, especially the Arabs, were the masters of Afro-Eurasia. However, the most significant Muslim advances in these allied fields largely took place before 1000. After that millennial turning point, Arab geographic and cartographic knowledge was disseminated throughout much of Asia and into certain areas of Africa and Europe. Such great world maps (world in the sense that they showed Afro-Eurasia) as the Korean *Kangnido* of 1402, which showed the correct shape of Africa and depicted the Mediterranean Sea and the Black Sea as well as Western Europe, and the *Catalan World Atlas*, which was drawn in Majorca in 1375 and depicted both the gold route from Mali across the Sahara and a Chinese vessel along India's Malabar Coast, depended greatly upon now-lost Muslim maps. Possibly the most important single piece of cartographic knowledge passed from Dar al-Islam to the Latin West was the notion of the shape of the world, which Muslim scientists had learned from Hellenistic treatises and Arab and Persian sailors from experience. The early-thirteenth-century *De sphaera mundi* (*On the Sphericity of the World*), a treatise that drew largely from the writings of the ninth-century geographer al-Farghani, was read as a text at the University of Paris. Such widely disseminated knowledge allowed even persons not trained in a university, such as Christopher Columbus, to imagine that the Far East could be reached by sailing west.

The one area where theory and practical experience and application met most fruitfully was medicine. Whether via Greco-Arab medicine, native Indian *ayurveda* (the science of longevity), Muslim-Indian *unani*, European medicine, Native American forms of herbal and surgical intervention, or traditional folk healing, including shamanistic intercession, human beings around the world probably had as good a level of medical care available to them as they ever had had or would have until the triumph of the germ theory and modern clinical training and practices that originated in Europe and America in the late nineteenth century.

—Alfred J. Andrea

■ Introduction: The Advances and Limits of Medieval Science

Human societies throughout the world had traditions of thought about nature. However, the modern conception of “science” as a secular, rational endeavor had not fully emerged. Science was treated as connected with religion or magic in many cultures. In many non-literate cultures, healing was connected with the powers of shamans or holy men and women.

Even in literate Christian Europe, the universities in which work in “natural philosophy” occurred were church institutions, and a goal of natural philosophy was illuminating the glory of God.

Medieval science had not fully severed its links with magic. Astronomy remained strongly associated with astrology. Astrology was also

linked with medicine, as it was believed that a responsible physician would schedule medical treatments for the astrologically correct moment. Chemistry in its form of “alchemy” often combined experimental procedures with magical rituals. Both Islamic and Christian religious authorities often looked dubiously on such procedures, but they remained widely practiced none the less.

The most secular and rational traditions of science existed in China and to a lesser extent in the Islamic and Christian worlds, where researchers in science and medicine were heirs to the traditions of classical Greece. Arab thinkers, the most active followers of the Greek tradition in the early Middle Ages, virtually invented optics and advanced mathematics, astronomy, and medicine as well as many other disciplines. Their work had impact not just on their own civilization, but on that of Latin Christendom, where Arabic and Greek works previously translated into Arabic were often translated into Latin, and India, where Unani medicine built on the Greco-Arab medical tradition. The Arab world also served to disseminate the Indian numeral system to Christian Europe, where it proved far more useful to scientists and technologists than was the previously dominant Roman numeral system.

Islamic, Byzantine, and Latin Christian science built on the Greek tradition, but did not usually go beyond it by challenging its fundamental assumptions. The authority of the ancients—Ptolemy in astronomy, Aristotle in physics, and Galen in medicine—remained paramount, even after their systems were substantially modified, as the physicists of late medieval Paris and Oxford introduced new ideas about motion, including mathematical treatments that would eventually influence Galileo. The geocentric universe of Ptolemaic astronomy and Aristotelian cosmology remained the template for medieval scientists. The ideas of the ancients were most likely to be challenged or denied in those areas where they were incompatible with monotheistic religion in the Abrahamic tradition. Aristotle’s doctrine of the eternity of the universe, for example, had to be decisively rejected as incompatible with the belief in the creation of earth and the universe by an omnipotent God. (Some religious leaders, such as Etienne Tempier, the bishop of

Paris, or the Sufi theologian al-Ghazali, went beyond attacks on specific doctrines to suggest that the scientific enterprise as a whole teetered close to impiety.) Religion also helped set the agenda for scientists, as Christians wrestled with astronomy to determine the correct date of Easter, or Muslims with trigonometry and cartography to establish the *qibla*, the direction of Mecca to which Muslims were required to orient themselves in prayer.

—William E. Burns

Astronomy and Astrology around the World

Between 1000 and 1500 CE astrology played a central role in the lives of untold millions around the world. Native peoples of North America organized their year around the movements of celestial bodies, while their neighbors to the south—principally the Maya and Aztec peoples—closely studied the heavens for insights into divine will. A conviction that terrestrial life was in some way dependant upon the stars and planets was so pervasive that it would be impossible to summarize in a manageable space. However, the attitudes and practices of three cultures—the Indians, Muslims, and Chinese—can tell us much about the way that learned people perceived and practiced astrology around the globe.

The ancient Indians saw nature as a manifestation of the divine. More specifically, the heavenly bodies were seen as deities, prompting an abiding curiosity that was inseparable from their conception of sacred duty (*dharmā*). Thus, the *Rig Veda* demonstrates knowledge of the five planets visible to the naked eye as well as a fairly sophisticated understanding of solar, lunar, and the diurnal motion of the earth that may date to as early as 3,000 BCE. Given this fascination with the heavens and the identification of celestial bodies with divinities, it is not surprising that there arose a belief in the affective influence of the heavens over terrestrial affairs, which in turn gave rise to a predictive science: *vyotisha*, commonly rendered as *vyotish* by Western scholars.

Vyotish rapidly attained a position of prominence in the celestial sciences. By the time that Sripati (1019–1066) wrote his *Jatakāpaddhati*, the work that would become the standard text-

book for generations of Indian astrologers, his hierarchy of disciplines was hardly contested. For this influential scholar, mathematical astronomy—meaning the study of celestial motion and the concomitant mathematics involved with understanding these motions—was important primarily as a tool for making astrological predictions more accurately. The astrological system of the *Jatakapaddhati* does betray some Greek influences, which is unsurprising given that by the seventh century works such as the *Romaka Siddhanta* were introducing Western concepts to the East. However, Indian mathematics was already far too advanced to allow slavish imitation or wholesale copying of Greek models. Rather, the introduction of Ptolemaic astrology and astronomy acted to promote innovative thought. For example, Indian scholars developed a theory of epicycles that was likely inspired by Ptolemy but involved a model of planetary motion based upon variable circumferences of these epicycles that allowed for more accurate predictions of the positions of planets.

There was no stigma attached to the practice of predictive astrology in India. In fact, the highest caste of society—the Brahmin—supplied the majority of astrologers. These men could be found at all noble courts holding well-paid positions and offering advice on subjects ranging from marriage to war. The most visible expression of the esteem enjoyed by these scholars is the massive collection of eighteenth-century astronomical instruments known as Jantar Mantar at Jaipur, India, built by the Maharaja Jai Singh II to ensure the greatest accuracy possible for his court astrologers. This compound represents a type that had been constructed for centuries, though never on this scale.

Other societies were less accepting of astrology. Within the Muslim world, opposition to this predictive art had originally centered on a presumed association with *kabhan* (diviner priests), whom tradition relates that Mohammad had denounced. In time, disapproval became focused on the idea that astrology's predictive element was incompatible with free will. However, by the eleventh century the rise of the Asharite school of theology, with its emphasis on Allah's control over every aspect of human life, undercut traditional Islamic belief in humankind's freedom of

➤ ASTRONOMIC INNOVATION IN AL-ANDALUS—AL-ZARQALI

Al-Andalus was one of the great intellectual loci of the Middle Ages. Perhaps the most important astronomer to emerge from this period was al-Zarqali (1029–1087), known in the Latin West as Azarchel. Working in Toledo, he built a number of precision instruments to aid in his work, which he used to make observations of the heavens that were astounding for their accuracy. For example, he measured the motion of the aphelion—the movement of the earth to its farthest point from the sun relative to the fixed stars—at 12.04 seconds per year, strikingly close to the modern measurement of 11.8 seconds. Al-Zarqali applied his skills in constructing tables showing the daily position of all the planets, allowing for the prediction of solar and lunar eclipses in addition to a wide variety of celestial motions and phenomena. Gerard of Cremona (ca. 1114–1187) translated al-Zarqali's works into Latin in the twelfth century, wherein they provided the basis for the *Toledan Tables*, the most accurate compilation of astronomical data available until they were revised as the *Alfonsine Tables* a century later. In this way the work of the great Andalusian astronomer al-Zarqali came to be the basis of astronomical and astrological work in the West until the sixteenth century.

—Scott Hendrix

choice. In spite of this, religious antagonism toward astrology not only deepened but became more organized. According to authorities, astrology promoted sinful pride by pretending to give humans access to God's mind.

While this opposition complicated the lives of astrologers, judicial astrology's promise was too great for it to be banished from noble courts and the lives of the moneyed classes. Under the caliphate, astrologers regularly provided advice on questions of war, succession, and even when the best time might be to conceive a male child. Wealthy merchants had no trouble finding a skilled student of *ilm abkam al-nujum* (the science of the decrees of the stars, namely astrology) who could provide advice on investments, when to begin a trade journey, or a variety of personal questions.

In contrast to the Arabic world, *tianwen* (portent astrology) enjoyed immense prestige in Chinese culture. Monarchs appointed court astrologers and tasked them with assiduously gathering information on celestial phenomena to ensure that the ruler's actions were in tune with the Mandate of Heaven that had placed him in power. Since deviance from this natural order could spell disaster for not only the ruler but for his realm as well, the grand astrologer—who functioned as the head of what was, in essence, a department of astrology—was one of the most important advisors at the imperial court.

However, astrology was restricted to the court. Viewed as essential to the well-being of the state, the knowledge and tools necessary to the astrologer were strictly controlled. As such, learned astrology was not accessible beyond the immediate circle of the emperor. From at least the time of the Tang Code, established in 624, practice of astrology beyond this exalted circle was punishable by death. In practice, this meant that there were three centers of astrological practice in China from the tenth century until the thirteenth century, with this number being reduced to one with the reconsolidation of China under the Mongols in 1279. With Khubilai Khan's promotion of traditional Chinese culture in order to promote himself as holder of the Mandate of Heaven, the importance of astrology to imperial control of China became more important than ever. However, by this time Chinese astrology had absorbed many Arabic and Indian influences, adopting the use of the horoscope, for example, in place of the traditional system based strictly upon an analysis of planetary position in relationship to the balance of the traditional elements: metal, wood, water, fire, and earth. The result was a system that was increasingly complex yet decreasingly open to modification based upon empirical observations. By the sixteenth century the resultant creation was more of a metaphysical structure, inviting reflection upon the spiritual characteristics of a subject of analysis rather than a scientific one requiring objective analysis of collected data.

Abd al-Rahman al-Sufi's *Treatise on the Constellations (Kitab suwar al-kawakib al-thabita)*

Composed in the Iranian province of Shiraz in 964, Abd al-Rahman al-Sufi's illustrated handbook on the constellations became a major reference work for astronomers as a catalogue of star positions. Several renowned scientists owned copies that survive to this day: Nasir al-Din al-Tusi (1201–1274) in Maragha, Iran; Amir Ulugh Beg (1393–1449), the grandson of Timur i-Leng and ruler of Samarqand; and Taqi al-Din Misri (1526–1585), a scholar in Ottoman Istanbul. Written in Arabic, the treatise is a systematic account of all 48 classical constellations, ranging from the northernmost figures (starting with Ursa Minor) to the 12 Zodiac constellations and those of the Southern Hemisphere. Each constellation is illustrated separately as a line drawing with the stars painted in numbered circles laid across the figure. Al-Sufi's images are therefore legible not only as single figures but also as functional star maps, depicting localized parts of the celestial sphere. Given this, there is often a strong correlation between the constellation iconography in al-Sufi's treatise and that of the celestial globes produced in the Islamic world, and indeed several globes credit the treatise overtly.

Perhaps surprisingly, each of al-Sufi's constellations is illustrated twice, first as seen in the sky and then as seen on the globe. This double format was designed to assist the student and is a unique and innovative feature of al-Sufi's treatise. On a typical celestial globe made in the medieval Islamic world, the outlined constellation figure was depicted as a mirror image of the same constellation when actually perceived in the starry sky, so al-Sufi's double format shows both viewpoints together for clarity. Many copies of the treatise tend to show these two versions on either side of the same page, which is a perfect way to explain this tricky issue as explained by al-Sufi himself in his treatise. The connection between these two sky and globe

versions may thus be understood by simply lifting up the illustrated page to the light. By turning over the page, the same figure can be seen from either side, demonstrating globe and sky view alternately.

Although they derive from a late classical iconographic tradition, al-Sufi's images are usually drafted with reference to the stylistic conventions of then-contemporary Islamic art; thus, Orion and Sagittarius are often depicted wearing turbans. In translation, the classical constellation names were also subject to metamorphosis in the Islamic period. In this context, Greek mythological identities were practically meaningless, so proper names such as Perseus and Cassiopeia were often discarded for more descriptive versions of the posed figures: Cassiopeia became *dbatt al-kursi* (the seated woman), and Perseus became *hamil ra's al-ghul* (the holder of the demon's head).

Together, al-Sufi's text and illustrations combine a star catalogue modeled on Ptolemy's *Almagest* and a comparative discussion of the two different systems of star names used by scientific astronomers and by Bedouin Arabs. Typically, the illustration of a classical constellation (such as Perseus, Orion, or Hercules) is overlaid with small inscriptions noting corresponding star names in Bedouin astronomy. For the most part, these Bedouin star names refer to completely different associations of identity, such as the gazelles visualized over the stars associated with the classical Ursa Major. Other instances imply a shared heritage from ancient astronomy, such as the Bedouin identification of a lion, scorpion, and male figure close to or overlapping the classical constellations of Leo, Scorpio, and Orion. While the Bedouin star identities are normally indicated only by inscribed labels, at least three Bedouin constellations are directly illustrated in al-Sufi's treatise, usually overlapping a classical figure: the Horse, the Fish (overlapping Andromeda), and, less frequently, the female Camel (overlapping Cassiopeia).

The cultural contrast is not only between different identifications for stars and constellations but also between a written scientific heritage (the textual sources of classical astronomy, mobilized from Greek and Persian into Arabic during the period of intellectual activity known as the Translation Movement) and oral tradition (much of

➤ THE EARLIEST COPY OF AL-SUFI'S TREATISE

There are numerous manuscript copies of al-Sufi's treatise on the constellations, the finest of which is also the earliest known and dates to 400 AH (for the Latin *Anno Hegirae* meaning "in the year of the Hijrah") or 1009–1010 CE. Now held at the Oxford Bodleian Library (Marsh 144), this version of the manuscript was copied and illustrated by the astronomer's son Husayn, probably in the family's native Rayy in Iran. It is 213 pages long, an almost complete copy of the text; is beautifully copied in a clear Arabic script known as *naskh*; and features 77 exquisite illustrations of the classical constellation figures.

The quality of the Bodleian images proves that book illustration was already at a sophisticated level in the Islamic Middle East at this early period. Although written accounts describe formidable libraries and intellectual activity, surviving examples of illustrated books are rare until the late twelfth century. Although the constellations derive ultimately from a late classical tradition of scientific imagery, their long history of use in the Islamic world is apparent by the shift in iconography toward local costume details and figural types. Al-Sufi's constellation figures are drawn in an elegant style that strongly suggests a relationship with the pre-Islamic Sassanian art of Iran, particularly in the elaborate swirling costume folds. This archaism is probably deliberate. Al-Sufi served the Buyid dynasty, formidable patrons of science and culture who were keen to cite their Iranian heritage with reference to an imperial Sassanian ancestry both in their titles, reviving as they did the grandiose title *shahinshah* (king of kings), and in their art. The archaic style of the 1009–1010 manuscript may be part of that deliberate dynastic propaganda.

—Moya Carey

Bedouin star knowledge was preserved in rhyming verse for easier memorization). Al-Sufi's intercultural approach is typical of the intellectual syncretism of the scientific culture in the Islamic world. His patron, the Buyid emir Adud al-Dawla (d. 983), was a keen sponsor of intellectual activity and built several institutions in support of learning, including a large library accessible to scholars, hospitals, and an observatory.

Science and Medicine in Byzantium—A Case of Cultural Interchange

Between 1025 and 1204, Byzantine scholars revived learned science and medicine as an integral part of an intellectual life grounded in classical philosophy and applied it to essential problems. Fundamental questions in the history of Byzantine science and medicine are still unanswered, but the stereotype of Byzantine science as passive copying of classical texts is gone. Scientists and physicians used Islamic discoveries and developed model medical institutions. Despite thirteenth-century setbacks in the study and application of medicine, the sciences, and mathematics, Byzantine scholars and practitioners revived interest in these pursuits after 1261, and this late Byzantine revival had a profound impact on the course of Renaissance and post-Renaissance scientific, medical, and mathematical advances in the European West.

As in other premodern societies, the boundaries between science and occult learning were indistinct and often controversial. Astronomy and

mathematics were essential to calculating astral movements for calendars, but they were also closely tied to astrology, the use of the stars to predict human activity. Similarly, alchemy flourished in late Byzantium and, like medicine, combined ancient theory with practical applications.

Science was integral to the eleventh- and twelfth-century Byzantine revival of learning. The leading intellectual of the eleventh century, the polymath Michael Psellus (1018–after 1081), and his circle emphasized the sciences in the academic curriculum. Psellus, who claimed that he alone revived the study of philosophy, defended his study of secular astronomy, physics, mathematics, geometry, geography, and medicine. His vast literary corpus includes treatises and letters on many of these subjects based on his reading of classical and late ancient texts. He argued that he studied astrology in order to refute its inappropriate uses but defended alchemy as a natural process.

While Psellus studied the sciences as philosophy, eleventh-century manuscripts demonstrate equal interest by others in applied science, especially in Arab learning. For example, Symeon Seth, who also wrote treatises on physics and medicine and translated fables from Arabic, referred to Arabic recipes in a treatise on diet, traveled to Egypt to view a solar eclipse, and was described as a mathematician and astrologer who was able to predict the death of Robert Guiscard in 1085 using a "new" method. Astronomical tables using the star calendars of Arab astronomers, astronomical compilations of Islamic origin, and even a surviving astrolabe all demonstrate Byzantine use of Arab advances. Byzantine scholars of the age traveled, used materials from Egypt, and were often themselves of Persian or Egyptian origin.

Controversy arose over astrology in the twelfth century. Byzantine rulers in this period frequently consulted astrologers, as did their Islamic and Latin counterparts, and scholars commonly differentiated mathematical astrology from less-acceptable occult practices. Emperor Manuel I Comnenus (r. 1143–1180), however, elicited strong condemnation from church leaders for his defense of astrology.

Geography and natural history were also revived in the eleventh and twelfth centuries

► PTOLEMY'S GEOGRAPHY

One of the most important Byzantine legacies to early modern Europe was its preservation of the *Geography* of Ptolemy (fl. ca. 130–175 CE), which provided the basis for the science of calculating geographical locations and representation on globes and maps of the earth and its regions.

Ptolemy's treatise, which included detailed descriptions of regional maps of Europe, Africa, and Asia, was translated into Arabic in the ninth century, but there is little evidence that it was used or studied in early Byzantium. The Greek manuscript was rediscovered by the Paleologan scholar Maximus Planudes (ca. 1255–1305), who had copies made, and although the manuscript that Planudes found is unknown, two copies of it survive. The Planudes manuscript, and apparently Ptolemy's original text, did not contain maps, but Planudes commissioned a conversion of Ptolemy's information into 26 maps. At least one manuscript arrived in Italy in the early fifteenth century and was translated into Latin, and the maps were copied in luxury editions. The *Geography* and the maps of Planudes became quite popular in fifteenth-century Europe and were copied in many manuscripts and appeared in early printed editions and atlases.

*Ptolemy's map of the world, printed at Ulm in 1482.
(Library of Congress)*

Ptolemy's calculations were incorrect, significantly underestimating the circumference of the Earth and overestimating the eastward expansion of Asia. Thus, it was Ptolemy's text and Planudes' maps that led Christopher Columbus and other early navigators to believe that the Indies were within reach by sailing west.

—Dorothy de F. Abrahamse

through commentaries on and quotations from classical writers. The twelfth century also saw significant developments in Byzantine medicine. Physicians appear in letters and other texts as professionals whose ability to diagnose disease and administer remedies was respected, in contrast to almost universally negative stereotypes in earlier centuries. Medical knowledge as an intellectual accomplishment is reflected in letter collections and in the writings of imperial figures, such as the princess and historian Anna Comnena (1083–after 1148). Medical and pharmacological manuscripts demonstrate a high degree of specialization in areas as specific as ophthalmology, diet, remedies for kidney stones, and pulse and urinary examination as well as in the incorporation of Arab medical knowledge and terminology. Specialized surgical instruments survive, and postmortem scientific dissection is also attested for this period.

The Byzantine hospital (*xenon*) flourished in the twelfth century as a sophisticated treatment institution. The imperial charter of Constantinople's Pantocrator Monastery describes its *xenon* in great detail as a 50-bed hospital with its own staff of salaried physicians whose specialties included ophthalmology, hernia repair, surgery, and pharmacology. They were instructed to wash their hands, keep patients warm, and provide separate beds for each patient. Women were treated in a special ward, and an outpatient clinic was attached to the hospital. Other hospitals existed in Constantinople and probably in provincial cities, although less is known about the latter. Compilations of medical writings, illustrated and used for training, and treatment lists developed by physicians survive from several hospitals. Leading *xenones* in Constantinople clearly offered sophisticated medical treatment to their patients far beyond the charitable institutions of late

antiquity or medieval Western Europe. The extent to which other Byzantine hospitals were comparable and the *xenon*'s relation to Islamic medicine and the development of hospitals in the Latin world are subjects for further research.

The concentration of learning in Constantinople heightened the disastrous impact of the Latin conquest of 1204 on science and medicine. Manuscripts were taken to the West or disappeared, and no hospitals survived the Latin occupation of Constantinople.

After the Palaeologean recovery of the capital in 1261, Byzantine scholars turned their energies to copying and annotating ancient texts. Most of the Greek classical texts in literature and science known today derive from these late medieval manuscripts. Significantly, however, these scholars emphasized the sciences, especially astronomy, mathematics, and medicine, in their revival of ancient learning. Theodore Metochites (1270–1332) and Nicephorus Gregoras (ca. 1290–1358–61) revived Ptolemaic astronomy; Gregoras also calculated eclipses and proposed calendar reform similar to the sixteenth-century Gregorian calendar. Persian astronomy reached Byzantium in the late thirteenth century through the translations of Gregory Chioniades (ca. 1240–ca. 1320), who studied in Tabriz, and for the next century astronomers concentrated on comparing and reconciling Persian and Ptolemaic calculations of longitude, eclipses, and calendars. Religious opposition to astrology continued, but most astronomical study was motivated by widespread interest in astrological predictions.

Medical study was also revived in the late empire. Hospitals were refounded on a smaller scale, although private practice was more common, and the treatment lists and medical treatises of earlier periods survive in copies used in the late empire. The tradition of scholarly medicine is represented by John Actuarius (ca. 1275–after 1328), chief court physician to Andronicus II Paleologus and the last great Byzantine medical writer, who wrote treatises on urine and the methods of medicine. Actuarius's letters describe his medical education and certification, visits to patients, and participation in a hospital. By the fifteenth century as the Byzantine state grew more precarious, scholars began to move to Italy, often with manuscript collections in hand.

By the fourteenth and fifteenth centuries, scientific and medical knowledge had become a transnational enterprise. Arab learning was transmitted to Byzantium by bilingual scholars who translated texts they had studied in Islamic centers. Although Europeans learned classical science primarily through Muslim Spain, multilingual settings such as southern Italy, Sicily, Byzantium, and the crusader states also served as centers of access to classical learning from the twelfth century on. The Dominican William of Moerbeke (ca. 1220–1286), for example, who spent much of his career in Frankish-held Greece, translated Aristotle, Archimedes, Proclus, and Galen and brought a large collection of Greek scientific manuscripts back to Rome.

Byzantine scholars made their greatest contribution to Western scientific and medical learning in the fifteenth and sixteenth centuries, as Greek classical texts, largely from Byzantine collections, became the source of Renaissance scientific discovery. Byzantine émigré scholars in Italy and their pupils taught Greek and oversaw the collection of manuscripts that became the core of the great Vatican, Marciana (Venice), and Nuremberg libraries. As Renaissance humanists sought and obtained original Greek texts, they were able to study, translate, and publish the works of Euclid, Archimedes, Apollonius, and Ptolemy, creating the basis for Western Europe's great mathematical and astronomical discoveries of the seventeenth century. Byzantine manuscripts of Aristotle, Hippocrates, Theophrastus, and Galen, translated and published in the sixteenth century, had a similar impetus on the natural sciences and medicine.

The Byzantine preservation of classical texts, so important for the history of Western science in the early modern period, was the result of successive scholarly revivals of secular learning beginning in the ninth century. But it is increasingly clear that in Byzantium, science and medicine also developed as empirical disciplines drawing on Islamic discoveries and participating in a Mediterranean exchange of learning.

The Oxford and Paris Physicists

Physics in the Latin West in the period 1000–1500 was largely dependent upon Aristotle's thought. In this Aristotelian scheme, the sublunar sphere (the realm beneath the moon, as opposed to the celestial realm of the moon and the planetary spheres) involved the study of optics and change but change of a particular character. Aristotle's system allowed for four types of change: change of place or position; change of substance, as when a fire converts a log to ash; change of quality, as when something changes color; and change of quantity. The type of change that medieval Latin physicists concerned themselves with was primarily (although not exclusively) the first, change of place, also called local motion. In Aristotle's view (which was therefore the common Greco-Roman and Arabic view), things in the sublunar sphere are composed of four elements: earth, water, air, and fire. Earth is the heaviest element, and fire is the lightest. Moreover, in the geocentric cosmos that he postulated, the earth is not only the center of the universe but is also immovable because the natural place of heavy bodies is at rest. Moreover, for heavy bodies smaller than the earth, their natural motion is to move downward until they are at rest. However, heavy bodies can also exert an upward (or violent) motion, called unnatural motion, as when a rock is thrown. On the opposite end of the scale, however, the natural motion of light bodies, such as smoke or fire, is upward. In addition, for Aristotle, since the natural state of a heavy body is at rest, anything that is moved is moved by an external force (such as the arm that throws the rock). The sole exception is animals, who have an internal means of motion (although Aristotle vacillated on this is-

➤ UNIFORM AND NONUNIFORM MOTION

In his *Rules for Solving Sophisms*, the logician William Heytesbury (before 1313–1372/1373), known as one of the Mertonian Calculators, applied his system of logical analysis to the issue of motion. Among his accomplishments was development of the Mean Speed Theorem, which postulates that a body moving at a uniformly accelerated speed (e.g., from 10 to 30 miles per hour) will cover the same distance in the same period of time as a body moving at a uniform speed equal to its mean speed (e.g., 20 miles per hour). Of course, this was purely theoretical because no medieval vehicle could hope to reach such speeds.

In the following selection from this work, he defined uniform and nonuniform motion.

"Although change of place is of diverse kinds, and is varied according to several essential as well as accidental differences, yet it will suffice for our purposes to distinguish uniform motion from nonuniform motion. Of local motions, then, that motion is called uniform in which an equal distance is continuously traversed with equal velocity in an equal part of time. Nonuniform motion can, on the other hand, be varied in an infinite number of ways, both with respect to magnitude, and with respect to time."

sue). The natural philosophers of the Latin West saw problems with this Aristotelian concept of local motion long before Galileo and Newton and attempted to address some of the issues, and in the process they discovered new means of analyzing and describing motion.

By the end of the thirteenth century in the Latin West there were two ways of addressing the nature of motion, or how things moved. One, advocated by the Andalusian Muslim Ibn Rushd (in Latin, Averroes, d. 1198), the German Albert the Great (ca. 1206–1280), and the Englishman William of Ockham (ca. 1285–1347), was called

forma fluens (flowing form), which maintains that a moving body simply occupies successive places at successive times but that there is no specific thing (or quality) called “motion” in the body that causes it to move. The other theory, called *fluxus formae* (flux, or change, of form) maintains that there is a quality called motion within the body that causes it to move. This theory was defended by John Buridan (ca. 1295–ca. 1358) at Paris in the fourteenth century and was adopted by most natural philosophers of the time.

There was also a further division of physics into kinematics (i.e., describing motion mathematically) and dynamics (i.e., determining the causes of motion). Gerard of Brussels in his early-thirteenth-century *Book of Motion* implicitly made the distinction between the two, but the Oxford scholar-clerics at Merton College explicitly made the distinction and excelled in kinematics in the fourteenth century. The main Mertonians were William Heytesbury (fl. 1335), Thomas Bradwardine (d. 1349), John of Dumbleton (d. ca. 1349), and Richard Swineshead (fl. 1340–1355), and they developed a discussion of motion kinematically, using the language of “intension” (an increase) and “remission” (a decrease) of the strength or degree of the “form” or quality (which could be speed or another attribute of change, such as temperature). The Mertonians also developed such concepts as velocity and instantaneous velocity as well as uniform and non-uniform (or what we call accelerated) motion. Moreover, although many scholars were unaware of it until recently, the fourteenth-century Oxford philosophers defined uniformly accelerated motion as it is defined today: A motion is uniformly accelerated if its velocity increases by equal increments in equal units of time.

A geometric representation of what the Mertonians had accomplished, which began around 1351 with the Franciscan Giovanni di Casale, was continued at the University of Paris by Nicole Oresme (d. 1382), who excelled at it and whose geometric representations are (arguably) forms of early graphs. He used a horizontal line to represent the subject, or extension, line and used vertical lines to represent changes in intensity of any quality, such as speed and temperature. Although Galileo never gave credit to his prede-

cessors at Oxford and Paris, he was well aware of their work, for it shows up in his own.

Arguably the most important issue in dynamics, the analysis of the causes of motion, concerned the motion of projectiles, such as rocks or arrows, particularly once they left the projector (e.g., once the rock left the hand). Although it seems obvious enough to us, it was not obvious to those schooled in Aristotelian physics and familiar with Aristotle’s principle that “everything that moves is moved by an external force,” according to which once the rock left the hand it should simply fall to the ground, since there was no longer any visible external force acting upon it. Aristotle got around this by arguing that the agent of motion (the hand) also endows the air (the medium) through which the rock moves with the ability (energy) to cause motion in order to keep the rock moving. This argument did not satisfy some fourteenth-century natural philosophers. John Buridan postulated the theory of impetus (and coined the term) to describe this force behind the rock, which he also claimed as the cause of the acceleration of falling bodies, arguing that as a body falls its weight generates more impetus, which in turn generates greater velocity. The theory of impetus, particularly regarding projectile motion, remained dominant until the seventeenth century.

The study of optics was significant for many fields in addition to physics, including astronomy, medicine, theology, epistemology and cognition (how one acquires and processes knowledge), philosophy, and so on. Late-twelfth-century translations of the optical works of Euclid (ca. 325–ca. 265 BCE), Ptolemy (ca. 90–168 CE), and al-Kindi (in Latin, Alkindus, ca. 801–873) dealt with the more mathematical aspects of optics, while those of Aristotle, Ibn Sina (in Latin, Avicenna, d. 1037), and Ibn Rushd conveyed the physiological and psychological aspects of vision. Translations of works by Galen (second century CE) and the short treatise by the ninth-century polymath Hunayn ibn Ishaq (in Latin, Johannitius) on the eye dealt with its anatomy and physiology. However, the *Optics* of Ibn al-Haytham (in Latin, Alhacen, ca. 965–ca. 1040) had the most impact after it was translated around 1200. Al-Haytham approached the issue broadly: mathematically, physiologically,

anatomically, and from the point of view of physics. His work would be adopted and passed on by the Franciscan Roger Bacon (ca. 1220–ca. 1292). Bacon's theory was more complex, however, because he added a Neoplatonic idea to the mix by arguing that every object radiates a force or image of itself outward. In short, Bacon combined Aristotelian, Arabic, and Neoplatonic influences to produce not only an important theory of vision and light but also an influential new philosophy of nature.

Bacon's fellow Franciscan John Pecham (d. 1292) and Witelo (d. ca. 1281) also passed on Alhacen's theories, and Alhacen and Bacon greatly influenced discussions of light and vision in natural philosophy and the related field of cognition from the fourteenth century to the time of Johannes Kepler (ca. 1600).

Arabic Medicine

Although Arabic medicine remained firmly based in its Greco-Roman foundations, there were many advances between 1000 and 1500 CE. From the School of Hippocrates of Cos (fifth century BCE and following) and from Galen (d. 216 CE), who represented the pinnacle of the Hippocratic tradition, the Arabs inherited the idea that the health of the body is based on the four humors: blood, phlegm, and yellow and black bile, which

had corresponding temperaments of sanguine, phlegmatic, choleric, and melancholic, respectively. Moreover, the Greeks also posited three major organs, the heart, liver, and brain, each housing a vital faculty and producing a vital spirit (*pneuma*). (The spleen was added later, bringing the number to four, because in the Greco-Roman tradition, symmetry was exceedingly important.) The heart, the seat of the animal (or vital) faculty, governs respiration and emotion and produces the vital spirit, which travels through the arteries. The liver, the seat of the natural faculty, governs growth and reproduction and produces the natural spirit, which is dispersed through the veins. The brain produces the psychic (or nervous) *pneuma*, which spreads throughout the nerves and is also the location of the psychic faculty controlling thought and sense perception.

The human body was viewed as a microcosm of the universe. For diagnostic purposes therefore, in addition to the corresponding temperament, one of the four cosmic elements (earth, air, water, and fire), two of the four primary qualities (wet, dry, cold, and warm) that were associated with the particular element, and one of the four seasons were likewise assigned to each humor. For example, blood (sanguine temperament) was associated with the element of air as well as with the primary qualities hot and wet and with spring. Moreover, the months of the year (distinct from those of the seasons), the signs of the zodiac, and the human ages (childhood, adolescence, adulthood, old age) figured into the system as well.

For the body to be healthy there had to be a balance among the humors, which could be affected by, or even restored by, manipulation of the six nonnatural environmental factors: surrounding air, diet, sleep, exercise, mental (emotional) state, and retention or evacuation of waste. These factors were discussed in detail by Ibn Ridwan (d. ca. 1068) in his treatise *On the Prevention of Bodily Ills in Egypt* as well as by al-Mukhtar ibn Abdun ibn Butlan (d. ca. 1068), a Christian practicing in Baghdad, in his *Almanac of Health (Taquim as-Sibbah)*. The latter even recommended music to soothe the patient and improve recovery. The balance was also

➤ IBN AL-NAFIS AND THE “LESSER PULMONARY CIRCULATION”

Ala al-Din Abu al-Hasan Ali ibn Abi al-Hazm al-Qarshi al-Damashqi, better known as Ibn al-Nafis (1213–1288), was born in Damascus and educated in Islamic law, literature, and theology as well as medicine, which he learned at the Nuri Hospital in Damascus. He moved to Egypt in 1236 to practice first at the al-Nassri Hospital and then at the al-Mansuri Hospital, eventually becoming chief physician as well as personal physician to the sultan. Ibn al-Nafis wrote, among other treatises, an original work on ophthalmology and began an encyclopedia designed to comprise 300 volumes, left incomplete at his death. His most famous work was a summary of Ibn Sina’s *Canon* titled *Mujaz al-Qanun* (*The Summary of the Canon*). In a discovery made in 1924 of a manuscript in which Ibn al-Nafis commented on the anatomy of the *Canon*, he contradicted the Galenic model that was accepted up to that point, that the blood flowing into the right cavity of the heart seeps through the septum to the left side of the heart, where it mixes with air and then disperses to the rest of the body. Ibn al-Nafis argued instead that the blood flows from the right ventricle to the lungs, where it mixes with air and then returns to the left ventricle of the heart via the pulmonary vein. His discovery, incorrectly termed the “lesser pulmonary circulation,” was virtually unknown in Islamic lands and passed to Europe apparently

Ibn al-Nafis discovers lesser pulmonary circulation in the fifteenth- or sixteenth-century, painting by Bihzad. (Musée d'Histoire de la Médecine, Paris, France/The Bridgeman Art Library)

when some of his works were translated into Latin in 1547 by Andre Alpago of Belluno. It is possible that this was the source for Michael Servetus and Andreas Vesalius (*De Fabrica*, or *On the Fabric [art or work] of the Human Body*, 2nd ed., 1555), who described pulmonary circulation in the sixteenth century. William Harvey confirmed Ibn al-Nafis’s description of pulmonary circulation in 1628.

—Kimberly Georgedes

maintained by phlebotomy (also called venesection, commonly known as bloodletting), and cupping (putting a heated cup over small cuts on the skin to draw blood).

The *Canon of Medicine* of Ibn Sina (known in the Latin West as Avicenna, 980–1037) became the most significant encyclopedic compendium that combined Greek medical knowledge and philosophy with Arabic commentaries and contributions. In five books, Ibn Sina covered various topics such as the methods of diagnosis, the six nonnaturals, hygiene, anatomy, tumors, fevers, fractures, pharmacology, and even a treatment for those in love. Ibn Sina’s work, although certainly the most significant, was one of many encyclopedic works common in Arabic medicine.

Arabic medicine excelled in many ways, not least of which was in the development of the hospital, which reached a peak in the twelfth and thirteenth centuries. The most prominent of the hospitals were the Nuri hospital in Damascus, named after its founder, the twelfth-century Turkish governor of Syria Nur al-Din ibn Zengi (1146–1174); the Mansuri in Cairo (completed ca. 1284 and founded by the Mamluk sultan al-Malik al Mansur Qalawun); and Baghdad’s Adudi, which was established in the late tenth century but destroyed by the Mongols in 1258. The earliest record of a hospital in Al-Andalus (Islamic Spain), however, dates to 1397 in Granada. These hospitals had separate wards for male and female patients, a pharmacy, often separate facilities for

surgery, ophthalmology, gastrointestinal afflictions, the mentally ill, a lecture hall, and occasionally a library (which indicates their importance for medical education), and accommodations for staff, which included not only doctors but pharmacists, orderlies, stewards, and both male and female attendants. Although hospitals were often managed by a political appointee without medical knowledge, the staff physicians and the chief physician were usually quite competent in their fields.

One field in which Arabic medicine excelled was ophthalmology, particularly in the twelfth and thirteenth centuries. Khalifah ibn Abi al-Mahasim al-Halabi (fl. 1256–1275 in Syria) wrote *The Sufficient Book on Ophthalmology* (*Al-Kitab al-Kafi fi al-al-Kuhl*), which encompassed both previous writings and new Arab developments as well as illustrations of instruments needed for surgical procedures on the eye and eyelids. Both trachoma (chronic inflammation) and cataracts were leading causes of blindness and were often treated surgically, although without much success. Although medieval Islamic doctors are often credited with being the first to remove cataracts, the primary method of treating them was called couching, by which the lens was pushed aside. Procedures on the eyes were very painful, and even the great physician al-Razi (Latin Rhazes, 865–925) preferred blindness to having his cataracts couched.

Surgery, although based on the ancients, also advanced in Muslim lands. Abu al-Qasim al-Zahrawi (Latin Albucasis or Abulcasis, ca. 940–1013, active in Cordoba, Spain), based his *Book of Concessions* (*Kitab al-Tasrif*, ca. 1000) on the work of the Alexandrian Paul of Aegina (seventh century CE) but nevertheless included much new practical information on anatomy, obstetrics, gynecology, pediatrics, and midwifery. His work also dealt with various aspects of surgery, including removal of tumors; cauterization; incisions; phlebotomy; fractures; methods for exploring both the chest cavity and the urinary tract, the latter to remove stones; and suturing methods and materials. He is also significant for devising and illustrating over 200 surgical instruments, including gynecological instruments. Ibn al-Quff (ca. 1233–1286), a Christian Arab,

wrote the first treatise devoted solely to surgery (excluding ophthalmology), titled *Basics in the Art of Surgery*. His work contains detailed descriptions of surgical procedures and treatments, particularly of wounds and tumors, and drug regimens. Al-Quff is also sometimes credited with the first description of the capillary system, although this is disputed. Muhammad al-Shafrah (d. 1360) also wrote a treatise devoted solely to surgical treatment of wounds and fractures but seemed more concerned with treatment by drug therapy. It should be noted that in many manuals the descriptions given are simply those from ancient sources, with no indication that they were actually performed, or as in the case of the tracheotomy, both Ibn Zahrawi and Ibn Zuhr (Latin Avenzoar, d. 1162) stated that they knew of no one who had performed it in their own day. There are other instances, however, when it is clear that descriptions are based on practice, such as the tonsillectomy and the treatment of wounds.

Advances in diagnosis and treatment are evident in the *Book of Simplification* (*Kitab al-Taisir*) by the Andalusian Abu Marwan ibn Zuhr (known in the Latin West as Avenzoar, d. 1162). He is credited with being the first to describe mediastinal tumors (those in the area between the lungs), and pericarditis (inflammation of the lining of the heart). Ibn Zuhr placed great emphasis on observation and practical medicine and thus was critical of Ibn Sina's *Canon* as being too theoretical.

Developments in pharmacology were a necessity. Originally pharmacology was based primarily on Dioscorides' first-century CE *De Materia Medica* (*On Medicinal Substances*) and Galen's *On the Powers of Simple Drugs*, but since many of the substances they described were not known to the Middle East, Islamic doctors learned to improvise with substances common to their climate. In addition to the earlier work of al-Kindi (ca. 800–870), al-Razi, and Ibn Sina's *Canon*, one of the important early texts of this period was that of Abu ar-Rayhan al-Biruni (943–1078), whose *Kitab as-Saydalah* (*Book of Pharmacology*) detailed the duties of the pharmacist. Two of the most important formularies (detailing the preparation of various drugs) were those of Ibn al-Tilmidh (d. 1165), used in Baghdad, and that of

the Jewish pharmacologist Ibn Abi al-Bayan (d. ca. 1240), which was used in hospitals in Egypt and Syria. Abu Jafar al-Ghafari, a twelfth-century Andalusian, was significant as well for updating drug properties and expanding knowledge of medicinal plants in his *al-Adwiya al-Mufrada* (*On Simple Drugs*). Ibn al-Baytar (ca. 1190–1248), another Andalusian who traveled widely, wrote the *Comprehensive Book on Simple Drugs and Foodstuffs*, which became the guide to all later Arabic pharmacopoeia. In it he not only clarified and corrected Arabic translations of Dioscorides' work but also detailed over 1,400 different drugs, using 260 different sources, in addition to observation. It was arguably the most important pharmacological work of the period. Developments in toxicology, the identification of poisons and their antidotes, were also made.

Physicians were generally highly esteemed in Islamic lands and were also generally well trained and well known in other disciplines such as law, philosophy, or theology, as in the cases of Ibn Sina, Ibn Rushd, and the Jewish polymath Moses Ben Maimon, known in Arabic as Ibn Maymun and to Latin students of his work as Maimonides. Many of their works were translated into Latin and had a substantial effect on Western medicine. Nevertheless, because there was no common education or licensing system for doctors in Islamic lands until the Ottoman period due in part to Islamic law, charlatanism was something of a problem about which many legitimate physicians complained.

Development of Indian Medicine—Ayurveda

The period just before the end of the first millennium of the Common Era witnessed the first major intrusions of Arabs into the heart of the Indian subcontinent. These were followed by the Turco-Afghan invasions of the Ghaznavids and Ghurids, which finally led to the establishment of the first Muslim dynasty in Delhi under the Mamluks (1206–1290). Incidentally, this period is also seen as coinciding with the decline of the *ayurvedic* system of medicine, which by this time had established itself as a popular medical tradition in India. The argument proffered by historians supporting this line of thinking was that the Muslim rulers of India were opposed to ayurvedic medicine, which was of Hindu origin, as compared to *unani* medicine, which was Greco-Arab in character and origin. However, the results of current research clearly contradict these arguments.

The ayurvedic system, as is now accepted, was not discriminated against under the rule of the Muslim monarchs ruling in different regions of India. Indeed, ayurveda (the science of longevity) continued to flourish and coexist along with the unani medical tradition under the patronage and political support of different rulers between 1000 and 1500. Ayurvedic doctors (*vaid*s) ran private clinics that were open to people irrespective of caste or creed, and this was also a period that witnessed widespread interaction between unani and ayurveda. Both were based on the theory of humors (four according to unani and three for ayurveda) and saw the cause of disease in humoral imbalance. Similarities between the two extended to such areas as the methods of diagnosing ailments and medicines.

This era witnessed the production of important compilations of ayurvedic texts in the form of *nighantu* (glossaries of therapeutically useful medicines) and commentaries. The focus was on expansion through innovation. Ayurvedic scholars of the period enlarged the existing medical lexicon by including a number of drugs which

found no mention in the ayurvedic texts and treatises of earlier periods. Significant among the many ayurvedic texts compiled during the period were Sarangadhara's *Sarangadhara Samhita*, Lakshmanacharya's *Vaidyavallabha*, Chakrapani Datta's *Dravyaguna Samgraha*, Lolimbaraja's *Vaidyavatamsa Lagbunighantu*, and *Yogaratanakara* by an unknown author.

Sarangadhara Samhita (*The Book of Sarangadhara*) was a thirteenth-century treatise dealing with weights and measures vital for the accurate preparation of various medicines, decoctions (a medicinal entity that has been boiled down), pastes, powders, pills, and electuaries (drugs mixed with a sweetener). It also dealt with the effect of seasons on diseases and ailments and methodologies of diagnosis and prognosis, chiefly pulse-examination (*nadipariksa*) that it described exhaustively. Branches of medicine such as anatomy, physiology, and embryology also found special treatment in the *Sarangadhara Samhita*. However, Sarangadhara's important contributions to ayurvedic medicine were in the form of introducing unique medicinal and pharmaceutical formulations especially by bringing to light numerous new plants, which though indigenous were not popularly used for the preparation of drugs.

The *Vaidyavallabha* (named after the author's father, Vallabha) by Lakshmanacharya was a fifteenth-century work composed in South India that dealt with fevers of different types, bleeding piles, urinary diseases, tumors, gastric diseases, jaundice, and women's health and diseases. Chakrapani Datta's *Dravyaguna Samgraha* (*Collection of Medicinal Plants*), composed toward the end of the fifteenth century, contributed to a basic understanding of ayurvedic materia medica (its body of collected information regarding the healing properties of medications) by providing a detailed description of various drugs such as their types, forms, and structures; regional names; and habitats. Lolimbaraja, the author of *Vaidyavatamsa Lagbunighantu* (a short pharmaceutical collection), was a Hindu of Brahmin caste married to a Muslim lady, and his treatises reflect the composite culture that was developing in India due to the interface between the Islamic and Hindu cultures. He offered some innovative formulae for such ailments as cough,

➤ AYURVEDA TODAY

The two chief Indian systems of healing, namely ayurveda and unani, faced stiff competition from the Western medicine introduced by British colonial rulers, to the point that these systems of healing were relegated to the margins, if not erased altogether. However, these Indian systems of healing received renewed life in the postindependence period (i.e., from 1947 onward), when successive governments of free India promoted indigenous methods of medical care. They were given official recognition in various national health policies and programs and were accorded a status equal to that of the Western allopathic system in which medical doctors are trained.

In 1995, the government of India created the Department of Indian Systems of Medicine and Homeopathy. It was later renamed the Department of Ayurveda, Yoga & Naturopathy, Unani, Siddha and Homeopathy (AYUSH) in 2003. This wing of the government not only provided funds and encouraged research in nonallopathic systems of medicine but also set up and supported various educational institutions imparting professional training in these systems of healing. The twenty-first century has seen Indian systems of healing, especially ayurveda, transformed into a brand to reckon with in the global health care market. From being labeled a charlatan to becoming a revenue earner with wide cultural acceptability, the ayurvedic physician has come a long way.

—Salil Kader

bronchitis, and jaundice. The *Yogaratanakara*, dated to 1676, tried to present a systematic development of Indian medicine by analyzing other books on the subject. It was basically a book of therapeutics. It also explained the importance of pulse examination as a means of diagnosis.

Use of metals in the preparation of drugs was an important achievement of scholars of this period. The calcination, or powdering, of mercury and other metallic processes, which make them fit for pharmaceutical application, do not appear in the works of the earlier periods. This period, however, witnessed the use of metallic and medicinal preparations using mercury, probably under the influence of Arab alchemy, in which mercury played a vital role. Mercury

was recommended for ailments such as fever, diarrhea, jaundice, diseases of the lungs, and syphilis. We come across more than 15 books on this therapeutic metal and its healing properties in this period.

Development of medicine during this period was also reflected in the various translations that took place from Sanskrit and Arabic to Persian, the language of the Muslim courts. These translations further facilitated the mutual understanding of ayurvedic and unani doctrines among their practitioners during this period. A notable example is Hakim Asseli's translation of around 1,473 extracts of Vagabhata's *Astangabridaya Sambhita* (The Book of Eight Ayurvedic Branches) at the court of Sultan Mahmud I of Delhi (r. 1489–1511).

Development of Indian Medicine—Unani

The *Unani* system of medicine, also known as *Unani Tibb*, traces its origin to Hellenistic Greece, as is clearly indicated by the Arabic words from which it derives: *al-Yunaan* (Ionia, the Greek coast of Anatolia) and *al-tibb* (medicine). Beginning in the eighth century, a number of Umayyad and Abbasid caliphs showed a keen interest in understanding and promoting Greek philosophy, science, and medicine by inviting scientists, researchers, and translators to their courts and commissioning translation of all the Greek sciences into Arabic. They paid special attention to the natural sciences, such as botany and medicine. In a matter of about a century, most of the important extant works of ancient Greek science and philosophy were translated into Arabic, with Baghdad, Damascus, Cairo, and Cordova emerg-

ing as the major centers of such scholastic activity. In the process, the Greek system of medicine, distinguished by the Hippocratic humors and Galenic emphasis on observation and investigation of illness, experienced a great deal of amendment, improvement, and systematization under Muslim physicians and medical scholars, especially in the field of anatomy and surgery.

The classical exposition of unani theory and practice was the massive *Canon of Medicine* (*Al-Qanun fi al-Tibb*), which Ibn Sina (ca. 980–1037), Avicenna in Latin, published in Persia around 1025. Physicians within this Greco-Arabic system accepted the principle that the human body is composed of four elements—earth, air, fire, and water—and these four elements result in four bodily fluids, or humors: blood, phlegm, yellow bile, and black bile. Unani physicians further assigned the four humors temperaments, called *mizaj*. Blood was seen as hot and moist (air), phlegm cold and moist (water), yellow bile hot and dry (fire), and black bile cold and dry (earth). Each individual was supposed to have a unique humoral constitution, and changes in this constitution brought about a change in the health of that particular individual.

This syncretic system of medicine eventually arrived in India and established itself as an effective system of healing alongside the indigenous ayurvedic medicine. Though historical data on how unani medicine came to India are scarce, historians have adduced that it entered India along with Arab traders and the invading Afghan armies around the twelfth century. Medicine in general and unani medicine in particular were patronized in India by the ruling class irrespective of region and religion. *Hakeems* (unani physicians) from different parts of the Islamic world and *vaids* (ayurvedic physicians) from various parts of India were invited to Muslim and Hindu royal courts and were given impressive titles and paid handsomely by the monarchs. The first unani physician in India who is known to us was Ziauddin Abdul Rafi Hirwi, court physician of the last Ghaznavid ruler, Sultan Khusrav Malik (r. 1160–1186) at Lahore. The first work on unani medicine written in India was a Persian translation of Abu Raihan al-Biruni's *Kitab al Saydla fi al-Tibb* (*The Book on Pharmacy and Materia Medica*), translated by Abu Bakr Asfar al-Kashani

sometime between 1211 and 1229. Unani medicine thereafter made steady progress under various dynasties of the Delhi sultanate (1206–1526), important among them being the Khiljis (1290–1321) and Tughlaqs (1321–1398).

Ziauddin Barani, a historian and contemporary of the Tughlaq ruler Sultan Muhammad bin Tughlaq (r. 1324–1351), while discussing the unani physicians of the time wrote in the *Tarikh-i-Feroze Shahi (The History of Sultan Firoze Shah)* that “*Atibba* (unani physicians) of the Alai period (Khilji) had complete skill in medicine and there can be no comparison between them and Hippocrates and Galen in treatment of diseases. Such distinguished physicians were neither seen before nor would be found in the coming times.” Prominent unani physicians, surgeons, and oculists (eye doctors) who practiced their art during the reign of Sultan Alauddin Khilji (r. 1296–1316) had no contemporary peers anywhere in India. According to the Persian historian Muhammad Qasim Ferishta (1552–1623), there were 45 *bakeems* in the court of Sultan Alauddin Khilji. Describing the prowess of the master-physician Badruddin Damishqi, Barani writes that “God had bestowed such skill and capability on him that he could judge the course of the disease just by feeling the pulse of the patient and predict whether he was curable.”

Patronage of unani medicine continued under the reign of the most important Tughlaq ruler, Sultan Muhammad bin Tughlaq. According to the *Masalik ul Absar fi Mamalik ul Amsar (Travels of the Eyes into the Kingdoms of Different Countries)* by Shahabuddin Abul Abbas Ahmad, a native of Damascus who traveled across India around the fourteenth century, there were about 70 hospitals (Darus Shifa, or House of Cures) and approximately 1,200 *bakeems* throughout the state in Delhi during this reign. Moreover, the exchange of ideas and practices between the ayurveda and unani systems of medicine was a common phenomenon during the period. The brightest illustration of the blend of ayurveda and unani can be seen in the form of the fourteenth-century text *Majmua-i-Ziai (Collections of Zia)* compiled by Hakim Zia Muhammad in 1336. Sultan Muhammad was succeeded by Sultan Firoz Shah Tughlaq (r. 1351–1388). The various medical works compiled during his reign,

➤ THE THEORY OF UNANI MEDICINE

The Unani system of medicine is rooted in the Hippocratic humoral theory postulated by the Greek philosopher-physician Hippocrates. This theory supposes the presence in the body of four humors, namely blood, phlegm, yellow bile, and black bile. The red portion of fresh blood is the blood humor (*dam*), the white material mixed with blood is the phlegm (*balgham*), the yellow-colored froth on top is the yellow bile (*saфра*), and the heavy part that settles down is the black bile (*sauda*). According to Hippocrates, these humors make up the nature of the human body, and it is through these that a person feels healthy or otherwise. A person enjoys the most perfect health when these elements are perfectly mingled and in equilibrium. Pain is felt when one of these elements is in defect or excess or is isolated in the body without being compounded with all the others.

According to Unani principles, the body has a power of self-preservation or adjustment called *Quwwat-e-Mudabbira* (Vital Force), which helps in maintaining the humoral balance. A weakening of this power causes an imbalance in the humoral composition, thus causing disease. Therefore, diagnosis of disease in Unani medicine is based on the study of humors in the human body, and administration of medicine was aimed at strengthening the Vital Force, which would in turn help restoration of the humoral balance.

—Salil Kader

such as the *Tibb-i-Feroze Shahi (Medicine of Sultan Firoze Shah)*, *Tibb-i-Shihabi (Medicine of Shihab Abdul Karim Nagori)*, and *Rahat-al-Insaan (Relief of Man)* stand out as noteworthy examples of the royal patronage accorded unani medicine during the period.

Rulers of southern India also extended patronage to unani medicine. In the middle of the fourteenth century, Alauddin Hasan Bahman Shah (r. 1347–1358) established the Bahmani sultanate (1347–1538) in the Deccan region (southern India), independent of control from the Delhi sultanate. The Bahmani sultans promoted both the ayurveda and unani systems of medicine. Two physicians of repute who lived during the reign of Sultan Alauddin Hasan were Hakeem Nasiruddin

Shirazi and Hakeem Aleemuddin Tabrezi. Hakeem Shirazi was a philosopher-physician who had come to the Deccan from Persia and opened his dispensary in the Bahmani capital city of Gulbarga. He was also known to have taught medicine. Hakeem Tabrezi, another Persian physician, also taught and treated patients in Gulbarga. The fifth Bahmani ruler, Sultan Mahmud Shah (r. 1378–1396), encouraged the translation of certain ayurvedic texts into Persian. This work in Persian, called the *Tibb-i-Shifa-i-Mahmudi (Medicine of Sultan Mahmud Shah)*, was translated into three volumes.

Mahmud Gawan (1411–1481), a prime minister to the Bahmanis, was another important personality in the field of medicine in the Deccan. Gawan, also known as Khwaja Imaduddeen Mahmud Gilani, was also a scholar and man of letters. A much-traveled person who was educated in various countries, he ultimately reached the Deccan at the age of 42 and subsequently became the guiding light behind the famous *madrassa* (school) at Bidar, which was constructed in 1472. The madrasa was not only an architectural marvel but also a great center of learning. It is noteworthy that Khwaja Mahmud Gawan was himself well versed with the medical science of the period and encouraged studies in medicine at the madrasa.

Sultan Alauddin Ahmad II (1436–1458) was another Bahmani monarch who made a notable contribution to the field of medicine. The sultan constructed a hospital at the new capital city of Bidar that catered to the needs of the sick and indisposed. The hospital, which had both *vaid*s and hakeems to take care of the patients, was endowed with revenues from a number of villages. Unfortunately, this structure has fallen prey to the extremities of time and nature.

Despite having access to physicians who had a sophisticated understanding of the nature and course of various diseases and an advanced array of pharmacological aids, people continued to hold to traditional beliefs, especially when confronted with illnesses that were untreatable. “Evil spirits” were invariably the “cause” of such diseases, and amulets and talismans were seen as panaceas.

Chinese Medicine

Chinese medicine from 1000 to 1500 includes developments made in the Song dynasty (960–1279), the Yuan (Mongol) dynasty (1279–1368), and the early Ming dynasty (1368–1644). Medicine was still based on the *Huangdi Nei Jing (Yellow Emperor’s Classic of Internal Medicine)*, ascribed to the mythical Yellow emperor Huangdi (2698–2598 BCE) but probably composed or completed sometime in the Han era (202 BCE–220 CE). The work was conceptually based on the principles of *qi* (pronounced “chee” and meaning vital energy, something like the Greek *pneuma*), meridians (channels, or conduits, of fluids and energy), *yin* (representing the female principle, passivity, darkness, earth, dampness, cold, and interior factors), *yang* (representing the male principle, activity, light, heaven, fire, hot, dryness, and exterior factors), and the five elements of air, water, earth, fire, and metal. Health was based on the harmony of these factors within the body, somewhat like the balance of the humors within the Greek medical tradition. Buddhist, Daoist, and Confucian ideology each influenced medicine in various ways as well. Although reverence for tradition was significant, a great deal of progress in medicine was made beginning with the Song dynasty.

In 1076, the National Health Administration was reestablished, as well as the Imperial Medical College (and later provincial schools), which

taught the three medical branches—medicine, surgery, and acupuncture. In 1113, eight disciplines were established: general practice, internal medicine, obstetrics, ophthalmology, acupuncture, dermatology, dentistry, and surgery. Students took and were graded according to results of their examinations on various topics, including the principles of medicine and surgery as well as clinical medicine and surgery, diagnosis by pulse, and physiology and anatomy. Those of the first grade served in official positions, taught, or wrote textbooks. For example, a number of pharmacopoeia as well as the *The Imperial Encyclopedia of Medicine* (*Sheng Ji Zong Lu*, 1111) were written under government auspices. These positions were often assigned based on additional competitive examinations. Those of the second grade were licensed to practice throughout the empire. Those who scored lower than the second grade repeated their education, while those who failed outright changed occupations. The empire during the Song era also had laws governing medical practice, ethics, and liability. In addition, the state regulated the distribution of medicaments. Nevertheless, the effectiveness of the system depended on the emperors, and by the end of the Southern Song era (1127–1279) the system had degenerated, to be revived under the Yuan and Ming dynasties.

The study of acupuncture was a significant part of Chinese medicine. Although acupuncture was an ancient art, further advances were made in the Song period. In 1027 the emperor ordered Weng Wei Yi to cast two life-size bronze statues, complete with internal organs, meridians, and holes for acupuncture points. As a teaching tool, each statue was covered with wax and filled with water. Proper insertion of the needle caused water to leak out. Weng Wei Yi's *Xin Zhu Zhen Jiu Ton Ren Tu Jing* (*Classic Chart on the New Bronze Acupuncture Statues*) describes the points on the meridians and their functions. Subsequent significant works on acupuncture included Duo Mo's (1190–1280) *Poem to Illustrate the Deepest Secrets* (*Baio You Fu*), Hua Shou's *Elucidations of the Fourteen Acupuncture Tracts* (*Shisijing Fabui*, 1341), and Yang Jizhou's *Compendium of Acupuncture and Moxibustion* (*Zhenjiu daquan*, 1468). In 1443 the

Itinerant doctor visits a village, 1049–1130, by Li Tang.
(Photo12/The Image Works)

Ming government ordered the casting of acupuncture models similar to those of 1027.

The development of medicine was also affected by a school of thought called Li Xue (Theoretical Principle), founded by the neo-Confucian Zhu Xi (1130–1200). He maintained that there are two principles, *li* (pronounced “lee”) and *qi*, and that neither was found without the other. The *li* is something like the universal archetype, or pattern (cf. Platonic forms), and the *qi* is both that which produces and out of which things are produced (for example, the five elements). The *li* (also called the *taiji*, or “supreme ultimate”) when active produces *yang* and when passive produces *yin*, both manifestations of *qi*. The flow of energy is key to this theory. As a result of the application of this theory to medicine, the Song government issued a “calendar of Yun” detailing when epidemics might occur and what preventative measures to take.

Regarding the etiology (causes) of disease, in 1171 Chen Yan (also called Wu Ze) in his *San Yin Ji I Fang* classified causes into three types: internal (*yin*) factors, meaning emotional excesses; external (*yang*) factors, meaning environmental factors; and neutral, or miscellaneous, factors such as diet, accidents, animal bites, insect bites or stings, and so on (which are partly *yin* and partly *yang*). Chen Yan's work was based on the earlier work of Zhang Zhong Jing, also

THE GOVERNMENT AND PHARMACOLOGY

During the Song and Yuan dynasties the government became involved in regulating the disbursement of herbal medicines. The National Health Administration established the National Pharmacy in 1076, which patented herbal medicines and determined standard doses. Over the years, many national pharmacopoeias were published. A revised and enlarged edition of a tenth-century pharmacopoeia was published in 1057, with information on 1,082 herbal medicines under the title *Jiayou Ben Cao* (*The Jiayou Reign Period Pharmacopoeia*). The *Illustrated Pharmacopoeia* (*Tu Jin Ben Cao*) by Su Song (and others) was published in 20 volumes in 1061 and described 780 plants and 625 medicines. Although not itself sponsored by the government, Teng Shen Wei's (1056–1093) *Zhen Lei Ben Cao* (*Classified Pharmaceutical Natural History*, ca. 1082) included 476 new medicines in its total of 1,558 and became the basis for the government's new pharmacopoeia, the *Daguan Ben Cao* (*Daguan Reign-Period Pharmacopoeia*), which was revised in 1116, 1159, and 1249 with a new title each time. The *Tai Ping Hui Min He Ji Ju Fang* (*Formulas of the Bureau of People's Welfare Pharmacy*, 1107), by Chen Shi Wen (and others), is a formulary with 788 herbal medicines that also updated the manner of preparation, building upon the fifth-century CE work of Li Xiao. Proper preparation was necessary in order to detoxify, minimize side effects, and improve the effectiveness of various herbs. The *Formulas of the Bureau of People's Welfare Pharmacy* also made patent medicines both popular and more convenient.

—Kimberly Georgedes

known as Zhang Ji (150–219 CE), whose *Shanghan Zabinglun* (*Discourse on Fevers and Miscellaneous Illnesses*) was divided into two works during the Song period, the *Shanghanlun* (*Treatise on Febrile [Fever] Diseases*) and the *Jinkui yaolue* (*Essential Treasury of Medicine*).

Additionally, medical advances were ascribed to other schools of thought, including the *He Jian* School's Fire and Heat theory, the Zang Fu theory (Yi Shui School), the Tonify Earth School,

the Purgative School, and the theory of Primary Fire. Liu Wan Su (1120–1200) founded the He Jian school (named after He Jian, where he was born); initially called Fire and Heat, it was subsequently known as the Cold School or the Cool School. Su posited that *yin*, or cold-based, febrile (fever) diseases arising from excessive external factors (to which he added lack of care) were caused by and often transformed into (*yang*) fire and heat factors (hence, Fire and Heat theory). Thus, to treat such diseases, cold-property herbal medications should be used (hence, Cold, or Cool, School). The Zang Fu theory, set forth by Zhang Yuan Su, also known as Jie Gu (1151–1234), postulated that disease occurred with excessive or deficient cold or heat in the internal organs. He influenced pharmacology with his treatments, as he classified medicinal herbs into warm, cool, tonifying (rebuilding energy), and reducing (stagnant or excessive energy) and also discovered that one medicine could affect different organs in different ways. Moreover, he claimed that in each compound there is one herb that will direct the other components through a specific channel to a specific area or organ. Li Gao, also known as Li Kao or Li Tung Yuan (1180–1251), the founder of the Tonify Earth School, continued the development of the Zang Fu School but concentrated on the spleen (*yin*) and stomach (*yang*) organs as those wherein most disease originates through deficient Yuan Qi (original vital energy, which originates in the stomach and spleen) due to fatigue, diet, or intensive emotions. Treatment consisted of herbal methods that would increase the Yuan Qi by warming the stomach and spleen and protecting the spleen against excessive *yang* and the stomach against excessive *yin qi*.

Zhang Cong Zheng, also known as Zhang Zihe (1156–1228), founder of the Purgative School and coauthor of *Parental Care according to the Way of Confucius* (*Ru Men Shi Qun*), maintained that external factors, especially diet, caused disease. His treatments involved purgation via diaphoresis (sweating) for skin problems, vomiting for upper body problems, and colonic purgation for those of the lower body. For each type he outlined specific treatments that included herbal remedies, acupuncture, massage, and

moxibustion (applying cones of mugwort to the skin and lighting it to cause a blister).

Zhu Zhen Heng, also known as Chu Tan-chi or Chen Heng (1281–1358) followed the Li Xue philosophical school and created the theory of Primary Fire (Xiang Huo), which is located in the heart and is the primary life force and source of health. Excessive fire (*yang*) results from activity that, if unchecked, burns out the original *yin*. When the primary fire is at rest, the body is healthy. Successful treatment decreases the excessive *yang* and increases the *yin*, hence his Nourishing *Yin* theory.

Diagnosis using the pulse was improved upon in the Song and Yuan periods by Cui Jia Yan and Shi Fa, the latter of whom published a work in 1241 with 33 illustrations and also classified the 24 types of pulses and what they indicate in a new way (although ultimately 51 types of pulse would be distinguished). The first treatise devoted entirely to diagnosis by observing the tongue was that of Du Ben, who also included 36 charts.

Advances in surgery were made with the works of Li Xun (1196), Yang Shi Ying (1264), and Chen Zhi Ming, who wrote the first work concerned solely with surgery in 1266. The government published *Sheng Ji Zong Lu* (*Comprehensive Collection of Surviving Techniques*, 1111–1117), which advocated primarily drug therapies for treating surgical problems. Qi De Zhi (1335) summarized advances for the period. During the Yuan period, works appeared dealing with bone fractures and dislocations. Advances were also made in ophthalmology, obstetrics, and pediatrics.

The Chinese also produced possibly the earliest work in forensic medicine, the *Washing Away of Wrongs* (*Xiyuanlu*) by Song Ci in 1247 as well as possibly the first steroid. In addition, the Chinese became adept at diagnosing and treating smallpox—the first treatise devoted entirely to smallpox was the *Tou chen lun* (*Treatise on Smallpox*) by Wen-jen Kuei, published in 1223—and are credited with inoculating against it possibly as early as the tenth century, at about the same time as the practice is thought to have begun in India, but the earliest documentation is from the sixteenth century.

Western Medicine

The revival of Western medicine between 1000 and 1500 began at Salerno in southern Italy in the mid-900s and spread northward. Subsequently, with the eclipse of Salerno in the early thirteenth century, the medical schools at the universities of Montpellier in southern France, Bologna in the northern Italian region of Lombardy, and Paris became Europe's major centers for the study of medicine.

The Latin West retained some practical and theoretical knowledge of Hippocrates of Cos (fifth century BCE) and Galen (d. 216 CE) throughout the early Middle Ages, but it was the translation movement associated with the intellectual revival of the eleventh and twelfth centuries that most influenced the development of medicine as an academic discipline. This was due to the translation from Greek not only of additional works ascribed to Hippocrates and Galen but also of certain important medical works from the Muslim world.

Constantine the African (d. 1085/1087), a convert from Islam and a monk at Monte Cassino, was the first translator to affect the Western Latin medical world with his translations of short works on urine, diets, and fevers by Isaac Israeli (Ishaq ibn Sulayman al-Israili, d. ca. 932), an Egyptian Jew; the *Isagoge* (*Introduction*) of Johannitus (by which the *Introduction to Medicine* by the ninth-century Arab Christian Hunayn ibn Ishaq was known in the West); Hippocrates' *Aphorisms*, *Prognostics*, and *Regimen in Acute*

Diseases; and Galen's commentaries on the latter two. Moreover, Constantine translated three compendia, or encyclopedic works—Galen's *Megategni* (*The Great Art of Healing*), the *Pantegni* (*The Universal Art of Healing*) of Haly Abbas (Ali ibn al-Abbas al-Majusi, fl. ca. 983), and the *Viaticum* (*Handbook*)—as well as the *De Coitu* (*On Intercourse*) of Ibn al-Jazzar (d. 980). Gerard of Cremona (d. 1187), who moved to Toledo, Spain, to learn Arabic, translated many medical works from Arabic into Latin, including Ibn Sina's (Latin, Avicenna, 980–1037) *Canon of Medicine* and al-Razi's (Latin, Rhazes, d. 925) *Book for al-Mansur*. Translators in Toledo and Italy added numerous other medical works, including those of al-Kindi (d. after 870) and Abu al-Qasim al-Zahrawi (Latin Abulcasis or Albucasis, fl. ca. 1000), the latter of which were important for surgery. Latin translations of both Greek and Arabic works continued into the Italian Renaissance.

As might be expected, Salerno was the first significant center of medicine in the Latin West to use these translations. Before its eclipse as a major medical center, it was well known for its skilled medical practitioners, which included clergy and “the women of Salerno.” The most well-known of the latter was the twelfth-century Trota (or Trotula), to whom is attributed a famous work on gynecology, although this is disputed. During the eleventh and twelfth centuries, the Salernitans made progress in the areas of anatomy, surgery, and pharmacology. Anatomy was taught by dissecting pigs and the bodies of humans discovered drowned or dead by other causes. Such study led to developments in surgery as evidenced in Salerno's *Bamberg Surgery*, which dominated the field until the emergence of two master surgeons and their much-studied works: Roger Frugardi (fl. before 1180 in Parma, d. ca. 1195), who composed the *Practica Chirurgiae* (*The Practice of Surgery*), and Guy de Chauliac, who authored the *Great Surgery* in the late fourteenth century. The Salernitans incorporated Islamic pharmacological principles into their medical science and even surpassed them to some degree, as evidenced in the *Circa Instans* (*Concerning Instants*) of Platearius and the *Antidotarium* (*Antidotes*, ca. 1150) of Nicholas, among others, along with their commentaries.

Salernitan practitioners and teachers also compiled the *Articella* (*The Little Art of Medicine*), a collection of short treatises that formed the basic teaching curriculum in the late twelfth and early thirteenth centuries. It was composed of Hippocrates' *Aphorisms*, *Prognostics*, and *Regimen in Acute Diseases* and one or two Galenic commentaries on Hippocrates as well as Galen's *Ars Parva* (*Small Art [of Medicine]*), Johannitius's *Isagoge*, and two short Byzantine tracts on diagnosis by study of urine and pulses (supplemented in the fourteenth century with works by Avicenna, Rhazes, Haly Abbas, and more of Galen).

The Salernitans taught the *Articella* by commenting on the various works and were also the first to emphasize the importance of Aristotle's scientific works for medicine. The *Articella* quickly became the standard medical text throughout Latin Europe, especially after the legacy of Salerno passed to the north in the early thirteenth century.

Medicine was being taught at Montpellier from the mid-twelfth century, and medical masters and students incorporated themselves into a university there by 1220 in order to grant recognized degrees. Evidence exists for medicine emerging as a discipline at Paris at about the same time as Montpellier and the university's offering of a license (degree) in medicine between 1270 and 1274. Medicine emerged at Bologna between 1200 and 1220, thereby eclipsing Parma as a center of medical education, and the organization of medical students and masters into a university probably took place before 1260. Other less prominent centers of medical instruction included Oxford, Padua, and Ferrara. As an academic discipline, medicine was taught within an Aristotelian framework, which led to philosophical and theological discussions of medical questions and conflicts between Galenic and Aristotelian physiology, which were not readily resolved philosophically or theologically.

With the offering of university medical degrees by the late thirteenth and early fourteenth centuries, there developed an informal hierarchy of medical practitioners, with university graduates at the top, commanding the highest salaried positions. Below them were skilled practitioners and then skilled surgeons (surgery was often con-

sidered a technical craft rather than a science to be taught in the university), followed by barber-surgeons, herbalists, apothecaries (druggists), midwives, and others. The terminology concerning the medical profession was significant. A doctor (teacher) always meant a university graduate who was licensed to teach in the area of his expertise, namely the arts, theology, law, or medicine. The term “doctor” did not necessarily mean someone who practiced or taught medicine. The term “master” might mean a university graduate, although not necessarily. The term *medicus* referred to either a physician or skilled surgeon. The term *physicus* meant a physician but only implied a medical degree and an acquaintance with natural philosophy (that is, physics, or *physica*), but in the vernacular it meant a general practitioner of internal medicine (also called *physica*, or physic), as opposed to a surgeon. Finally, the term “empiric,” a derivative term, meant someone who had no formal education but acquired general medical knowledge by practice. Both university graduates and skilled practitioners would have a working knowledge of Latin, but the others generally would not. Nevertheless, there was quite a body of medical literature in the vernacular (even most midwives would be literate enough to read them), and many Latin works were translated into the vernacular as the period went on. Municipalities and rulers undertook to license those practitioners, even those with degrees, in order to ensure some degree of competency, and in some areas guilds of physicians developed. Interestingly, it was the elite physician who had a general practice, and the specialist was often of lower status.

Practitioners, in addition to Christian laymen, included women, Muslims, Jews, and clerics. Although the Church forbade clerics to enter medicine merely for the sake of temporal gain and also forbade absenteeism from monasteries or parishes for the sake of medical studies, the Church was not opposed to clerics studying medicine in itself. In 1215, however, the Fourth Lateran Council forbade clerics to practice surgery without a papal dispensation because it involved the shedding of blood. Although women were excluded from obtaining university degrees, many were nevertheless licensed to practice, but

➤ POPE JOHN XXI (R. 1276–1277) AS PHYSICIAN

Peter Juliani (also known as Peter of Spain), philosopher, theologian, physician, and cleric, was born in Lisbon circa 1215, the son of a physician named Julian. Juliani went to the University of Paris for advanced studies in philosophy and theology and possibly studied medicine at Montpellier or Salerno. Although more well known for his philosophical works, such as his textbook on logic, the *Summulae Logicales*, that became the major text on logic for centuries to come, he was also a physician who wrote more than 20 medical treatises and taught medicine at the University of Siena, circa 1244. While in Siena, he became concerned with such things as city sanitation, hygiene, living conditions, and diet and how they affected a person's health. It was also in Siena that he came to the attention of church prelates, which led to advancements in the Church and ultimately to his election to the papacy in 1276.

Two of his major medical works are the *Liber de oculo* (*Book on the Eye*, ca. 1250) and his *Thesaurus Pauperum* (*Poor Men's Treasury*). The *Book on the Eye* deals with the anatomy of the eye (as it was then understood) and its diseases as well as treatments. The *Poor Men's Treasury* is a collection of inexpensive, easily prepared remedies for common ailments. Written in simple Latin for a wide audience, it also included prescriptions to enhance fertility, aphrodisiacs, and even 26 prescriptions specifically for contraception. The *Thesaurus Pauperum* was available well into the fifteenth century, when it was translated into English. His work *On the Eye* was quoted and used by others, including Michelangelo and the surgeon Guy de Chauliac (d. ca. 1370). Juliani was one of two popes whom Dante allowed into Paradise.

Pope John met an untimely end in Viterbo, when the roof of the study he was adding to his papal residence collapsed on him. He died a few days later, on May 20, 1277.

—Kimberly Georgedes

by the fourteenth century the movement to exclude women from practice was under way.

Some advances in anatomy occurred as the result of the practice of the dissection of human bodies, which appears to have begun in northern Italy initially as autopsies to determine cause of death for legal purposes. Venice allowed for

an annual dissection beginning in 1308 (although possibly not until 1368, by decree of the Great Council). The first recorded dissection of an executed criminal was conducted in 1315 by Mondino dei Liuzzi (d. ca. 1326), who taught practical medicine at the University of Bologna. He also wrote the *Anatomy*, published in 1316, that served as a dissection manual for the next two centuries. Nevertheless, although some universities and municipalities mandated human dissection for instructional purposes in the fourteenth century, particularly in northern Italy, it was difficult to obtain the bodies of executed criminals. Moreover, dissections occurred only during the winter due to rapid decomposition. Another reason that human dissections were rare until the late fifteenth century is that they added little to existing knowledge of human anatomy or to solving debates between Galenic and Aristotelian models of human physiology. Nevertheless, by the mid-sixteenth century it was common to use human corpses in anatomical instruction.

Diagnosis and treatment often proceeded according to the “complexion” and humoral theories described in the Hippocratic and Galenic corpus but further developed by Latin western European philosophical discussions in this period and aided by Arabic discussions, such as those found in Avicenna’s *Canon*.

From the twelfth century, Latin physicians referred to one’s “complexion” (Latin *complexio*, meaning “temperament”), which in this context referred to the combination and balance of the four elements (air, water, earth, and fire) and their associated primary qualities (hot, cold, wet, and dry) within the body. Ideally the complexion would be balanced, or “temperate,” typically discerned by touch, the palm being the most temperate area of the human body. Complexion, however, was also perceived as a somewhat relative quality, differing among species (plant or animal), individuals within species, and the parts (or organs) under observation. Among humans, what was considered normal would differ among races, their geographical regions, and individuals. One’s individual complexion was innate from conception, differed between genders, and was affected by the passing of time and external con-

ditions and circumstances (both material and environmental). Moreover, each organ was believed to have its own complexion.

Additionally, the four humors, or bodily fluids, originally articulated by Hippocrates and further developed by Galen, along with the Greek conception of the faculties and spirits (*pneuma*) associated with the three major organs, were significant as well. The humors consisted of blood, phlegm, yellow bile, and black bile, with their corresponding temperaments (not necessarily related to the complexion): sanguine, phlegmatic, choleric, and melancholic, respectively. The humors were important for nourishing the body and for maintaining the balance of the body’s complexion. The vital organs were the heart, brain, and liver (to which was sometimes added the genitalia), with their corresponding faculties (the vital in the heart, the psychic in the brain, and the natural in the liver), as well as the vital spirits produced by each (the vital, psychic, and natural, respectively). Maintaining balance within the complexion and among the humors and spirits was vital to the health of the body. Diagnosis, in addition to touch to determine the complexion (which was not always successful, as medieval doctors noted), included general observation of the patient, examining bodily excretions such as urine (which was used to determine the status of the liver), taking the pulse (which was used to determine the status of the heart), taking the patient’s history, and examining the astronomical and astrological signs. (Medical astronomy and astrology were a significant part of Western medical practice particularly from the fourteenth to the sixteenth centuries, as they were also in Islamic and Chinese medical practice, but Western doctors nevertheless were constricted by theological prohibitions against astrology.) When imbalance occurred, the most common treatment was by drug therapy and diet, although various forms of purgation and phlebotomy (also called venesection, or bloodletting) were also used as well as manipulation of the six nonnaturals, or factors external to the body, such as the air one breathes, sleep or lack thereof, exercise or lack thereof, diet, and retention or excretion.

Western hospitals in the period began primarily as places wherein the elderly, the ill, the

poor, the homeless, and pilgrims might find food, shelter, religious comfort, and sometimes, but not always, medical care, unlike Islamic hospitals of the period. As cities became more prosperous and hired doctors as civil servants, however, some were required to offer regular medical care in municipal hospitals. One of the largest of these municipal hospitals, but quite atypical for the period, was Florence's Santa Maria Nuova, which engaged nine physicians and offered 300 beds by circa 1500.

Guy de Chauliac—The “Father of Modern Western Surgery”

Surgeon and cleric, Guy de Chauliac (ca. 1295–ca. 1368) was born the son of poor French peasants around 1295 in Chauliac in southern France. Despite his origins, the Church recognized his talent, and under its patronage, he began and continued his studies. He eventually studied medicine and surgery at Toulouse and Montpellier, the latter where Henri de Mondeville taught and where Chauliac became a master of medicine and surgery around 1325. He pursued further studies in anatomy and surgery at the University of Bologna under Niccolò Betraccio (d. 1347), who was the protégé and successor of Mondino dei Liuzzi, the latter the author of the

THE CHIRURGIA MAGNA ON THE IDEAL SURGEON

The following statement demonstrates that Guy de Chauliac's vision of the ideal surgeon, written in 1363 in Latin, is as valid today as it was more than six centuries ago.

“The conditions necessary for the Surgeon are four: first, he should be learned; second, he should be expert; third, he must be ingenious; and fourth, he should be able to adapt himself. It is required for the first that the surgeon should know not only the principles of surgery, but also those of medicine in theory and practice; for the second, that he should have seen others operate; for the third, that he should be ingenious, of good judgement and memory to recognize conditions; and for the fourth, that he be adaptable and able to accommodate himself to circumstances. Let the Surgeon be bold in all sure things, and fearful in dangerous things; let him avoid all faulty treatments and practices. He ought to be gracious to the sick, considerate to his associates, cautious in his prognostications. Let him be modest, dignified, gentle, pitiful, and merciful; not covetous nor an extortionist of money; but rather let his reward be according to his work, to the means of the patient, to the quality of the issue, and to his own dignity.”

greatest manual of human anatomy and dissection until that of Andreas Vesalius in the sixteenth century. From Bologna, Chauliac traveled to the University of Paris for further studies, after which he began his practice in his home diocese of Mende. From there he moved his practice to Lyons, where he was also a canon, or ecclesiastical official, of the Church of St. Just.

His reputation as a physician and surgeon was such that he was invited to the papal court at Avignon, where he served as physician and chaplain to popes Clement VI (r. 1342–1352), Innocent VI (r. 1352–1362), and Urban V (r. 1362–1370).

He was in Avignon when the Black Death, otherwise known as the Bubonic Plague, struck Europe in the winter of 1347/1348. The plague wiped out a massive percentage of the population of Europe in its initial onslaught, which lasted until 1350. While other physicians, surgeons, and clerics fled from the plague, Chauillac remained with his patients, and carefully documented both the symptoms of the disease and his treatments. When Pope Clement VI refused to leave Avignon, Chauillac counseled him to remain in his rooms and keep large fires burning to stave off the plague. (Clement survived, although whether it was due to Chauillac's advice is impossible to know.) Chauillac himself contracted the plague in its second onslaught in 1360, but managed to survive. One of Chauillac's major contributions regarding the plague, however, is that he was arguably the first to distinguish clearly between the bubonic and the pneumonic forms of the plague, the latter of which affects the lungs and is passed through the air, has a much higher mortality rate, and a considerably shorter incubation period.

Chauillac is most famous for his *Chirurgia Magna* (*Great Surgery*), also called the *Inventarium* (*The List*), which he published in 1363, toward the end of his life. His work surpassed previous works as a compendium of medical and surgical knowledge up to this point. Indeed, Renaissance editors of his work noted over thirty-five hundred references and citations, not only of ancient and recent works but of works contemporary to Chauillac. More significantly, the work included Chauillac's own critical comments and conclusions based upon his own experience and observations. He was by no means a slave to tradition or authority, but as he wrote, "Socrates and Plato are my friends, but the truth is an even greater friend."

His work dealt with various aspects of medicine, including physiology, pathology and especially anatomy, in addition to surgery. As Chauillac noted, "A surgeon who does not know his anatomy is like a blind man carving on a log." Treatments recorded in his work include dealing with scalp wounds and skull fractures, and practicing trepanning (opening a hole in the skull to relieve pressure). He advocated removing foreign bodies from wounds (and various methods for

doing so) and disinfecting them using wine and spirits such as brandy, draining wounds to combat infection, closing chest wounds, and even operating for empyema (fluid in the pleural, or chest cavity), detailing where to make the incision, and resecting the ribs. He provides descriptions of different types of suturing, bandaging, and dressing the wounds, depending on the case. He recommended treating fractures of the femur by suspension and traction, and dealt with the trimming of open fractures, operating on hernias with sutures, rather than cauterizing them. (He also wrote a work dedicated specifically to the treatment of hernias.) Moreover, he was one of the first to tie off arteries and veins with sutures (again, rather than cauterizing them) to stop bleeding. He also discussed dentistry and dental instruments, and although he considered dentists specialists (*dentatores*), he nevertheless believed they should practice under the guidance of a physician.

Chauillac also produced works on astrology (closely tied to medicine in this period), and an apparently lost treatise on diseases of the eye, written ca. 1340. King John of Bohemia traveled to Avignon to have his remaining eye treated by Chauillac. John had already lost one eye to a disease (possibly a cataract), and drowned the physician as punishment. Chauillac also met with little success, but luckily escaped the punishment of his predecessor. King John was thenceforth known as "The Blind."

Chauillac died in Avignon sometime between 1368 and 1370. His *Chirurgia Magna* was influential in Europe until the seventeenth century, both in unabridged and in summary form in over a hundred editions, and was translated into several European languages. His description of the ideal surgeon is still quoted today by medical schools and associations.

The Medical Response to the Black Death

The response of physicians to the challenge posed by the 1348 disease outbreak known as the Black Death probably can be considered one of the most abject failures in the history of medicine. Admittedly, they did not have the technological and epidemiological tools that are taken for granted today, such as knowledge of such infectious microorganisms as bacteria and viruses and the application of vaccines and “wonder drugs” such as penicillin and other antibiotics. But this does not mean that they were entirely blameless for the mass deaths that took place under their care. Medieval doctors and their “cures” for the plague were not always harmless; quite often they made matters worse.

Hundreds of plague treatises penned in 1348 and for centuries thereafter by a variety of university physicians and other authors survive from nearly every country in Europe. No systematic survey of this impressive body of literature has yet been undertaken, but some preliminary conclusions can be offered. Judging from these treatises, the typical doctor was concerned with three issues: the cause of the plague, how to prevent the plague, and how to cure it. Surprisingly, doctors were little concerned with diagnosing the disease’s symptoms. When they did discuss symptoms, they usually did so in a theoretical way rather than from observation.

Causes of the plague were usually ascribed to bad air, following an explanation for disease known as the miasmatic theory. The notion of unhealthy miasma ultimately derived from ancient Greco-Roman medical authorities, such as Hippocrates and Galen, and persisted down to the nineteenth century. However, European physicians got most of their theory from Arabic mediators of ancient knowledge, particularly Ibn Sina (known in the West as Avicenna). Celestial disturbances and conjunctions of the planets were often seen as responsible for corrupting the air, although medical authorities also identified other sources, such as rotting corpses, fetid swamps, and earthquakes. Medieval doctors were also well aware that the disease could travel from person to person through breath or touch or, strange to modern sensibilities, by sight. It is im-

portant to realize that such theories of contagion did not preclude the miasmatic explanation. Indeed, the two went together in the medieval European mind, since an “aerial spirit,” the very breath of life within each person, could transmit infection from person to person.

Prevention of the plague revolved around the regimen of the six “non-naturals,” which were designed to block corrupt air coming into the body and ward off an imbalance or corruption of the four humors within the body. This theory also derived from the ancients and included prescriptions regarding how to avoid or “correct” bad air; which foods and drink to consume; how much exercise to take; how to sleep; how to purge the body of its excess humors, or waste matter; and even how to feel, on the grounds that violent emotion predisposed the body to infection.

The last section of most plague treatises, advice on how to cure the disease, was, not surprisingly, the shortest. By and large, doctors either prescribed bleeding the patient (also used as a preventative measure) in the hope of draining out the offending corruption or gave elaborate and numerous recipes for “theriacs,” syrupy concoctions designed to neutralize the plague poison. If bubonic swellings were present, physicians also advised first “ripening” them with a poultice and then drawing out the “poisonous matter” inside by cupping, cautery, or simply cutting them open. This was the closest that these medical practitioners ever came to performing surgery on plague patients.

Many questions remain regarding the medical response to the plague in 1348 and beyond. More detailed research into the surviving plague treatises will no doubt supply some answers, but this is still perhaps the last frontier in our knowledge about the Black Death, and its mysteries are tantalizing. One such mystery concerns some doctors’ claims to have successfully prevented or even cured the disease, even though a few physicians, such as Teobaldus Loneti, frankly admitted that the disease was “incurable.” Ibn Khatima, a Spanish Moorish physician, boasted in his treatise of 1349 that he kept “countless” people alive by bloodletting. How was this possible? It should be noted that he made this claim only for “therapy before the disease takes root”;

➤ ABU JAFAR AHMAD IBN KHATIMA, *DESCRIPTION AND REMEDY FOR ESCAPING THE PLAGUE*

A physician and poet from Almería on the coast of southern Spain, at that time part of the Muslim kingdom of Granada, Abu Jafar Ahmad Ibn Khatima wrote his plague treatise in February 1349, nine months after the plague arrived in Almería in June 1348. Although grounding himself in earlier theory, such as that of Hippocrates, Galen, and Avenzoar (Ibn Zuhr), Ibn Khatima also speaks from his own experience, even to the point of discussing specific cases, which was relatively rare in plague treatises. Khatima lived until at least 1369, when he is mentioned by his friend and fellow physician, Ibn al-Khatib.

“Therapy before the Disease Takes Root. . . .

Therefore, we found no easier and more successful treatment than bleeding, especially if it is performed immediately when there are signs of the disease, and before the fever takes hold and gruesome symptoms appear. As I’ve seen myself, I’ve had miraculous results by bleeding. The sooner it is done, the better chances the treatment has, and that is the main thing with this disease. . . . A fair amount of blood has to be drained, until the patient experiences a feeling of faintness, depending on strength and age. One mustn’t wait until the blood has a normal density or color; usually with this disease, it is thickened and black. Its characteristics won’t change, even if it were drained completely. Sometimes a thin, greenish liquid comes to the surface, or a grayish mass; that’s a very bad sign. If the patient faints before the proper amount is drained, sprinkle his face

and extremities with water until he comes back [to consciousness]; then finish the drainage. . . .

“A man from Homma Biggana, a village near Almería, came to me and told me that he and some twenty people from the village had fled from there for fear of the plague, which was ravaging the village. He complained about anxiety, depression, arterial cramps, which was his first indication of the disease. I prescribed an immediate bleeding, and twenty-two ounces of blood were drawn. He fully recovered, as if he hadn’t had anything. He went on his way, but only a block or two, and then he returned in an identical state as before the bleeding. I felt his pulse, observed him and saw the same symptoms. I ordered another bleeding, and this time eighteen ounces were drawn. This time he was fully free of fever, with only a little weakness, but he was able to walk home. He was rid of his pains and fully healed. I saw him later; he said he was the only one still alive from among those with whom he had fled. It all happened in one week. I don’t mention the story of this man as a rare triumph of bloodletting. My experiences in that field are countless. There are countless people, whose number God knows, who were kept alive by this measure. Thus is the might and will of God!”

Taha Dinanah, “Die Schrift von Abi G’far Ahmed ibn ‘Ali ibn Mohammed ibn ‘Ali ibn Hatimah aus Almeriah über die Pest,” *Archiv für Geschichte der Medizin*, 19 (1927): 60–63. Trans. J. Aberth.

once the disease had taken hold, treatment did not “make much sense.” Moreover, Ibn Khatima, as was true of his contemporary physicians, did no more than claim that he helped the body heal itself; any failures in treatment were put down to the patient’s own shortcomings, not the physician’s. It is also telling that he bled his patients—some of whom, incredibly, were alleged to have given up to eight pounds of blood—until they fainted. The lightheadedness that patients felt undoubtedly calmed them down, particularly those who hysterically (and mistakenly) anticipated coming down with the disease, and seemed to make them better.

Another mystery is why plague doctors continued to subscribe to outmoded theories of medicine when at least some, Ibn Khatima among them, pointedly noted that the morbidity and mortality rates of the disease were unheard of and unknown to the ancients. Raymond Chalin de Vinario went so far as to deride the ancients because they “plainly did not cure pestilential diseases, since they were ignorant of their causes.” Yet like so many of his colleagues, he cited Hippocrates, Galen, and Avicenna in his own discussion of the plague. Did medieval doctors feel that they had no other choice but to follow the line of what they had been taught? Were they

trapped by their own learning? Particularly maddening to a modern reader is the tendency of some plague treatise authors to go by the book even when the evidence before their eyes told them otherwise. An excellent example is the doctors' claim that the plague was most prevalent in the autumn, which made sense in theory since this was the cold and dry season that gave rise to melancholic humors. Yet almost all the surviving demographic evidence points to plague mortality peaking during the summer months. The Italian physician Gentile da Foligno provided an elaborate sixfold justification of this position for his students, yet he died of the disease on June 18, 1348, well before he could observe the plague's impact during the autumn. Whether later doctors ever learned from their predecessors' cumulative experience with the plague remains to be answered by further research.

Last, there is the intriguing role that magic might have played in plague medicine. This is perhaps the only original contribution that medieval doctors may have made to treatments of the plague, since magic ran directly counter to the rational tradition of most ancient authorities. Gentile da Foligno, despite his university training and grounding in the learned tradition, being particularly devoted to Avicenna, nonetheless flirted with magical remedies. One of his 11 medicines for treating the plague was a magic gold ring set with an amethyst inscribed with the image of a man holding a serpent, which he promised would "preserve you from any poison," including the "darts of pestilence." Yet Foligno cautioned that this remedy was "best kept in a book reserved for kingly persons," and he ascribed it to the heretic doctor Pietro d'Abano. Foligno also supplied detailed alchemical recipes for potable gold.

Concomitant with a willingness to use magic was the belief, championed by Foligno but not accepted by all his colleagues, that the plague was primarily caused inside the human body by a poisoning. A Spanish doctor teaching at the University of Montpellier in southern France, Alfonso de Córdoba, gives a detailed explanation of how an alchemical formula "prepared in a glass amphora" can be used to contaminate a whole city once it is broken and releases its vapor into a prevailing wind. One of the first Jews

to be accused in 1348 of poisoning wells in order to spread the plague to Christians, Balavigny of Thonon in Switzerland, also happened to be a surgeon. The twin themes of curing and causing disease through magical means, which fascinated some plague doctors, were to play a major role in the coming witch-hunt in early modern Europe.

In the popular imagination, the Black Death inevitably conjures up scenes of dead bodies lying in the streets. To this can now be added another gruesome image: rivers of blood running through the gutters, the result of nearly ubiquitous advice to purge patients by bloodletting. Bloodletting was not restricted to the wealthy or to residents of cities. The University of Paris masters of medicine recommended a phlebotomy most particularly for "the common folk and agricultural laborers, who do not lead delicate lives." Most writers of plague treatises assumed that people had access to a barber surgeon or, in a pinch, would perform their own bloodletting, as evidenced by Ibn Khatima's story of a "dissolute man" who decided to operate on his own boil on the groin, with disastrous results. In times of plague epidemic, doctors urged that the amount and frequency of bloodletting be stepped up. The typical advice was to double the number of phlebotomies that one normally received. Ibn Khatima even advised bloodletting two or three times a day, especially for caregivers of plague patients. Yet such extreme bloodletting undoubtedly weakened patients and made them more susceptible to the disease (even if it drained out some of the bacteria in the blood). Moreover, those who contracted plague symptoms were probably bled first; then all in the household who were healthy were bled as a precaution. Unfortunately, the surgeon or physician most likely used the same scalpel on everyone, even after having cut into plague boils. With no knowledge of germs, there was no perceived need for disinfection. When doctors advised washing the hands and face with water and vinegar, their intent was to ward off the bad air from the mouth and nostrils, not to disinfect. Thus, doctors, albeit unwittingly, helped spread the plague in the very act of trying to prevent or cure it, and they perhaps communicated the most deadly form of the disease, septicemic plague. Although rare in

modern times, it is commonly attested in medieval chronicles, and it seems to have been spread by a direct poisoning of the blood.

A full appreciation of the medical response to the Black Death may thus help elucidate the how and why of the plague's almost incredible virulence and mortality. The disease's epidemiological profile was shaped by humans' reaction to it.

Magic in Europe

In the European Middle Ages, magic encompassed systems of practice and of belief. The magician sought to understand or to harness supernatural powers to do his or her bidding through an array of practices such as astrology, alchemy, sorcery, and the use of charms. Magic was practiced by ecclesiastical and laypersons from all social and educational levels.

Medieval magic could be folkloric in character, usually transmitted orally, or learned by reading magical texts. Furthermore, magic was divided into angelic (white) and demonic (black), depending on the magician's desired results. Demonic magic, sometimes called necromancy, often conjured demonic spirits to assist the magician and sought to cause harm or deformity in another person or to manipulate the emotions of others to induce love or hatred. Angelic magicians sought to obtain heavenly or special knowledge, effect cures or recoveries from illness or

Theophilus enters into a pact with the Devil and then repents before the Virgin Mary, from the Psalter of Queen Ingeborg, about 1210. (Réunion des Musées Nationaux/Art Resource)

injuries, or gain a beatific vision (a mystical vision of God). Such magicians often invoked heavenly spirits to assist them.

The Church usually condemned magical practice. Beginning in the twelfth century, two related currents of intellectual endeavor helped to shape the Church's denunciation of magic. First, scholastic theologians elaborated cosmological doctrines that articulated the relationships between the natural and the supernatural worlds, declaring that demons influenced human action and identifying the power of magic in the natural world. Anselm of Canterbury (ca. 1033–1109) developed theories of the fall of the Devil. Writing in the first half of the thirteenth century, William of Auvergne (ca. 1180–1249), the bishop of Paris, condemned magical practices since they necessarily depended on demons who could de-

ceive the practitioner and cause injury. The greatest doctor of the medieval Latin Church, Thomas Aquinas (ca. 1225–1274), placed the Devil at the top of a hierarchy of evil spirits who worked to produce suffering and evil, both eternal and temporal. The weight of Thomas's intellectual authority solidified a framework for the understanding of magic that endured throughout the Middle Ages by clarifying that although some magic operated in the world through the agency of heavenly bodies, most often magicians drew on demonic forces.

The second development in the Church's condemnation of magic was systematic articulation of canon, or church, law concerning magic that linked it with the crime of heresy, or unorthodox belief. Around 1140 the great canon law scholar Gratian ranked magicians as sinners but considered their sin to be relatively mild. By the 1230s the Church had established the Inquisition, a special legal procedure created to find and eradicate heresy. In 1258 and again in 1260, Pope Alexander IV issued a letter that allowed the prosecution of sorcery using inquisitorial procedure if the magical activity had the appearance of heresy. Ironically, a bill of heretical charges brought by the French Crown against Pope Boniface VIII in 1303 in the midst of a nasty conflict of wills contained the indictment that he practiced "the demonic art." Believing that he had been a target of sorcerers, Pope John XXII propagated a bull in 1317 that attacked magicians. The Faculty of Theology at the University of Paris published a treatise on demonology in 1398 that claimed to prove the existence of demons and linked the practice of magic categorically with heresy, thereby opening the door for prosecution of magicians in inquisitorial courts.

Nonetheless, despite the Church's formulation of juridical and doctrinal theories against magical practice, interest in magic did not abate. Renaissance philosophers became interested in a magical tradition called Hermetic, so-called because its origins were ascribed to Hermes Trismegistus (Hermes the Thrice Greatest), a Greco-Egyptian deity of Hellenistic antiquity. Marsilio Ficino (1433–1499) and others believed that Hermeticism held the key to understanding the magical arts of alchemy, astrology, and other sources of wisdom.

➤ THE BLACK MAGIC TRIAL OF ETIENNE PEPIN, 1347

A mid-fourteenth-century case that exemplifies the use of magic in the realm of politics and the Church's use of inquisitorial procedure to try cases of magic is that of Etienne Pepin. In 1347 Etienne Pepin fashioned six pounds of virgin wax into the image of a man intended to resemble the bishop of the south-central French diocese of Mende, inscribed the bishop's name on the image, and wrote the names of six or seven angels across the chest. Pepin then hid the image in the wall of the chateau of the lord Guerin Apecher VI of Chateaneuf, a bitter enemy of the bishop. This sequence of events brought Pepin before the ecclesiastical court in Mende on the charge that he had used black magic to cause injury or harm to the bishop of Mende. Pepin confessed to these deeds and was sentenced under inquisitorial procedure to 15 years' imprisonment, sustained by only bread and water, in the episcopal tower.

—Jan K. Bulman

From its folkloric beginnings that were as old as Europe itself to the emergence of learned magic and the Renaissance interest in magic, magic endured beyond the Middle Ages. In fact, in the seventeenth and eighteenth centuries those interested in magic began to undermine intellectual reliance on Aristotelian traditions that helped to bring about what many historians call the Scientific Revolution.

Leonardo of Pisa

Leonardo of Pisa (ca. 1170s–ca. 1250), who sometimes referred to himself as Leonardo Bigollo or Leonardo Bigollo Pisani (“Bigollo” meaning “traveler” in the Tuscan dialect, or “man of no importance” in the Venetian dialect

➤ RABBITS, RABBITS EVERYWHERE! THE FIBONACCI SEQUENCE

The problem for which Leonardo of Pisa was famous is the seemingly inconsequential problem concerning the propagation of rabbits, found in Book 12 of the *Book of the Abacus*:

A certain man put a pair of rabbits in a place surrounded on all sides by a Wall. How many pairs of rabbits can be produced from that pair in a year if it is supposed that every month each pair begets a new pair which from the second month one becomes productive?

—Quoted in Mario Livio, *The Golden Ratio* (New York: Broadway Books, 2002), 96.

There would be only one pair during the first and second months, while they are maturing, but at the end of the second month the pair reproduces, and in the third month there are two pairs. The next month the mature pair has another, while the second matures, making three pairs. In the fifth month the first pair has another; the second pair, now mature, has a pair; plus the third still maturing make five and so on. The resulting sequence is 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144 . . . , in which the sum of the last two numbers produces the next.

There are many fascinating aspects to this sequence, not least of which is that the further one progresses in the sequence, the ratio between successive numbers moves closer to the Golden Ratio (ϕ , 1.61803398875 . . .). Nature exhibits the Fibonacci sequence in many ways, such as in leaf arrangement, the scales of the pineapple, the counterwinding spirals of the sunflower head, and the chambers of the nautilus shell. Edouard Lucas (1842–1891) named this recursive sequence (in which the relationship between successive terms can be expressed by a mathematical equation) the Fibonacci Sequence, the mathematical notation that was developed in 1634 by Albert Girard.

—Kimberly Georgedes

of Italian), is also known as Leonardo Fibonacci (“son of Bonacci”). He was the son of Guglielmo Bonacci, a customs official and representative of Pisan merchants in Bugia, North Africa (present-day Bejaia, Algeria), where Fibonacci learned mathematics and accounting with the Hindu-Arabic numeral system from an Arab teacher. Subsequent travels throughout the Mediterranean gained for him familiarity with other reckoning systems. In 1200 he returned to Pisa.

The work for which he is chiefly known is the *Liber abaci* (*The Book of the Abacus*, 1202, revised 1228) in which he argued for the superiority of Hindu-Arabic numerals and the place-value (decimal) system, with a symbol for zero as a placeholder. The concept of zero was significant, as it opened the possibility of discussing the value of the void, or nothingness, something that Aristotelian natural philosophy (science), which had a strong hold on Latin Christian thought at this time, denied with its dictum “nature abhors a vacuum.”

Although Gerbert of Aurillac, who became Pope Sylvester II (r. 999–1003), had studied mathematics and logic in Islamic Spain in the tenth century and had written a treatise on Hindu-Arabic numerals, he did not include a discussion of zero. The *Treatise on Calculation with Hindu Numerals* (ca. 825) by the ninth-century mathematician al-Khwarizmi (known in the Latin West as Algorizmi) was eventually translated into Latin before 1143, thereby introducing a system known in Latin as algorismus (the source of the word “algorithm”). Moreover, his *Compendious Book on Calculation by Completion and Balancing* (the word “algebra” derives from part of its Arabic title, *al-jabr*) was likewise translated into Latin in Spain toward the mid-twelfth century. Nevertheless, neither the use of Hindu numerals for calculation nor the concept of zero had yet taken hold in the West nor would they for some time to come.

Fibonacci’s familiarity with al-Khwarizmi’s work as well as that of the lesser-known al-Karaji (d. ca. 1029), is evident in the later chapters of the *Liber abaci*, where he presents and solves a number of sophisticated problems, the most famous of which (though not necessarily original to him) concerns the propagation of rabbits and results in what is called the Fibonacci Sequence.

Statue of Leonardo Fibonacci in Camposanto, the ancient cemetery annexed to the cathedral at Piazza dei Miracoli in Pisa. (iStockPhoto)

Around 1220 Fibonacci's work came to the attention of Emperor Frederick II of Hohenstaufen (r. 1215–1250), whose court mathematician, Jordanus, presented Fibonacci with a number of difficult problems, which he solved in a number of different, sophisticated, and ingenious ways. Fibonacci subsequently wrote three more works, *Practica geometriae* (*Practical Geometry*), circa 1220, and *Flos* (*Flower*) and *Liber quadratorum* (*Book of Squares*), both circa 1225, in which he demonstrated not only admirable knowledge of Euclid, Archimedes, and algebra (the latter from both al-Khwarizmi and al-Khayyami's *Algebra*) but also his own originality as a mathematician.

Although merchants found the Hindu-Arabic numerals to be a superior system for calculating and accounting, nevertheless municipalities and rulers were suspicious of the zero, for by adding a simple stroke, the 0 could be turned into a 6 or 9. Hence, many cities and kings outlawed the system. Nevertheless, the Algorists, as they were known, continued to teach and advocate the

Hindu-Arabic system, and merchants continued to use the system, even using Hindu-Arabic numerals to send secret messages (hence “cipher,” meaning “secret code,” from *ciphra*, *cifra*, *ze-firo*, *cefiro*, and other words for “zero”). By the early fifteenth century Brunelleschi (fl. 1425) used the vanishing point (the zero dimensional object representing infinity) to create three-dimensional perspective in drawing and relief sculpture. The numbers themselves took their modern form with the establishment of printing in 1453. By the late fifteenth century, zero was treated as a quantity in mathematics, not merely a placeholder. Not until the sixteenth century, however, did the Algorists fully prevail over the so-called Abacists.

Although Fibonacci, who began the revolution, had admirers in his own time, his genius was appreciated by few until after 1500.

Ritual and Shamanism in North America

Shamanism, from *shamán* and *hamán*, words borrowed from the Evenki and Eveny of Siberia, refers to a class of people who are able to diagnose and cure illness, control events such as the weather or movement of animal herds, and divine mysterious aspects of life and death through supernatural powers. Such powers are believed to derive from connections established between ritual specialists, helper spirits, and the Creator. A person with such gifts is alternatively called a medicine man or medicine woman, healer, doctor, or priest.

The powers of shamans derive from several sources including ancestry, dreams, visions, and places of power within natural landscapes such as mountains, caves, or canyons. Shamans also

► SHAMANISM AND PETROGLYPHS IN THE MOJAVE DESERT

Among indigenous New World religions, there is a frequent association of shamans, shamanic ritual practices, and the common mineral known as white quartz. At a small vision-quest site known as Sally's Rock Shelter located in the Mojave Desert of southern California, archaeologists conducted research that sheds light upon the nature of this association. Using a mixed-methods research approach that combined archaeological, ethnographic, and ethnohistoric data, researchers confirmed fascinating connections linking rock art, quartz rocks, shamans, and vision-questing activities. They found that certain rock art panels composed of petroglyphs (images created in stone by carving, pecking, or abrading rock surfaces) could be interpreted as the handiwork of shamans seeking supernatural powers.

In this quest, white quartz mineral played an important role. By comparing rock samples from diverse localities in North America, researchers learned that quartz is often found near quartz-free basalt rocks inscribed with petroglyphs. Further research revealed that when quartz is struck or abraded, it glows due to a quality called triboluminescence. When ritual specialists used quartz hammerstones to create petroglyphs depicting sacred experiences, including altered states of consciousness, the rocks would emit light. Shamans interpreted the glowing of quartz as a visible confirmation of supernatural powers.

—Alex K. Carroll

receive assistance through guardian spirits. These spirits may assume many forms including animals, reptiles, birds, insects, forces of nature such as the wind and the rain, and spirit beings that reside in the mountains, trees, rocks, or water such as the Little People and Water Babies. One Dakota chief explains that places in the landscape where the spirit of Wakan rested are considered very powerful. Such places are often selected for ritual activities and become increasingly powerful over time. Shamans are formally trained by more experienced shamans through dreams and visions. While shamans have principally worked alone in many North American tra-

ditions, in others, shamans perform their roles within the context of religious societies.

In North America, there are long-standing shamanic traditions. Some of the earliest material cultural connections to shamanic traditions are evidenced in rock art petroglyphs and pictographs believed to represent the altered states of consciousness of shamans living at least 8,000 years ago. The widespread presence of North American prehistoric ritual activities also is supported by evidence of ancient tubular pipes used for smoking tobacco, willow bark, and other natural herbs. Ritual specialists of North America have been smoking sacred tobacco and other herbs for millennia.

Whereas some rituals were established to meet the unique needs of a particular group, others were shared among multiple indigenous communities. For example, the mound builders of the Late Archaic, Woodland, and Mississippian periods, who lived 1,000 to 500 years ago, established ceremonial and trade networks involving numerous indigenous communities. Today, the convergence of diverse indigenous communities is evidenced in ritual practices such as the Sweat Lodge, the Sun Dance, and Powwows.

Shamans frequently use a number of sacred tools in the performance of public and private rituals. Some of the most frequently used items include rattles, drums, medicine staffs representing lightning or snakes, prayer sticks, medicine bundles, masks, fetishes, small animals carved out of stone imbued with special powers, feathers, and offerings of minerals, shells, or particular herbs. Sacred tobacco, sweet grass, and sage are among the many plants associated with ritual practice.

Some of the primary ritual activities that shamans of North America use to evince changes include prayer, dance, singing, dreaming, and fasting. Some ritual practitioners, particularly in southern North America, have traditionally ingested hallucinogenic substances such as datura or red harvester ants to induce an altered state of consciousness. In turn, each of these activities has been used to bring about multiple outcomes ranging from healing a person or community to bringing the world and all of its life forms into balance. Other rituals are performed to help the plants grow, ensure a successful battle, mark

Carved effigy pipes created by the Hopewell culture, or mound builders, of North America. (MPI/Getty Images)

cyclical events of the natural world, prepare for food quests, celebrate the earth's abundance, seek knowledge or wisdom, prepare for pilgrimages, assist initiates in undergoing rite of passage rituals such as coming of age ceremonies, welcome warriors back into a community, publicly acknowledge the union of new mates, or assist the soul of a person to cross over into another reality after the death of the physical body. Among the Paiutes and Hualapais of the Great Basin and Colorado Plateau, the journey to the other world begins by retracing a path along a traditional route known as the Salt Song Trail. Only after revisiting places of import via a series of songs sung over the course of a mourning ceremony is the soul prepared to leap from the known world into the afterlife.

The role of shaman is infused with great powers as well as weighty responsibilities. Among

the Paviotsos and Shoshones, for example, a medicine man or woman was held accountable for the people who died under his or her care. As a result, if three patients died, it was considered acceptable to kill the person who had treated them. Due to the capacity of a medicine person to potentially assist others, however, the shaman was and is held in high esteem among many of the indigenous communities of North America.

Health and Medicine in North America

At the time of European contact, each tribal group throughout the Americas had well-established indigenous health care delivery systems. Some had only one or two healers, whereas others had more complex systems, with an array of resources and specialists including midwives, bonesetters, herbalists, and so forth. Every family also had a family member who had extensive knowledge about home remedies, and each household maintained a formulary of herbs and other supplies for times of emergency. At the center of most tribal health delivery systems were healers whose knowledge and expertise enabled them to call upon both natural and supernatural resources to help restore health or to halt an individual's unusual bout of misfortune.

Tribal health care delivery systems were embedded in the sociocultural-religious fabric of each tribe. Consequently, most tribes shared a common set of cultural beliefs about health and illness, despite inherent intertribal cultural and

linguistic differences. The prevailing perception held by many tribes was that health is interconnected with morality and spirituality and that the well-being of an individual and of the community requires vigilant attention to maintaining harmonious relationships with nature and with other living beings. It was (and remains) believed that the disruption of this harmony can result not only in sickness but also in vulnerability to misfortune. To prevent illnesses and misfortune, tribal members strictly observed numerous tribal taboos and other moral codes. Other preventive measures included the use of talismans, medicine pouches, guardian spirits, and observance of certain important ceremonial activities.

Within the worldview of most tribes, nature was informed with spiritual significance. This spiritual significance was (and is) frequently embodied in certain landforms, such as sacred sites and sacred lands, as well as sacred objects, animals, and the like. For example, eagles, ravens, bowhead whales, buffalo, and salmon were (and

are) animals considered by some tribes as embodying not only spiritual significance but also the spirit itself. For that reason, certain animals served as guardian spirits or as a totemic sign for a particular societal group or clan. Members of the eagle clan, for example, might perform certain religious activities that call for help from the spirit of the eagle, which is their clan totem or guardian spirit. These relationships highlight tribal beliefs about the spiritual relationship binding humans, nature, and the spirit world. Such beliefs acknowledge that spirituality is transcendental in nature and can influence the manner by which one perceives, adjusts, or seeks remedies in times of ill health or misfortune.

■ Introduction: Expanding Knowledge of the World

The period between 1000 and 1500 was one in which a more certain knowledge of the physical and cultural face of Afro-Eurasia was disseminated by geographers and cartographers, as well as travelers who took care to give witness to their adventures.

Several phenomena spurred this expansion of geographic knowledge. First, there was the tradition of Arab descriptive geography and, to a lesser extent, cartography. Arab geographic writing had its roots in the eighth century, and a fair number of its most important works were written before the turn of the millennium. Arab geographers, however, continued to produce important texts well after 1000 CE, thanks largely to the expansion of Islam, in what has been termed the Afro-Asiatic Age of Discovery. Second, during the age of the Song, Yuan, and early Ming dynasties, approximately 960 to 1433, there was a substantial increase in Chinese long-distance mercantile activity, coupled with a shift

in focus away from Central Asian caravan routes to oceanic sea lanes. Third, an overall increase in long-distance commerce throughout the Levant (eastern Mediterranean), the Indian Ocean and its adjacent seas, and coastal China, to name only three of the most active areas, resulted in an increase in the number and size of diaspora merchant communities. Fourth, there was what has been termed the Medieval Expansion of Europe, in which, from approximately 1000 onward, Latin Europe extended its cultural, political, commercial, and imaginative range far beyond its earlier borders. Fifth, and most important of all, there was the thirteenth-century eruption out of eastern Central Asia that resulted in the Mongol empire and the consequent *Pax Mongolica*. Many previous entries and sidebars deal with aspects of these five phenomena in detail. Here, however, we must consider some of the more significant geographic texts and travel reports that circulated around Afro-Eurasia and several of the maps

that were crafted during this five-hundred-year period.

Arguably the greatest Islamic geographer was Abul-Hasan Ali al-Masudi (ca. 890–956), author of *Meadows of Gold and Mines of Gems*, a world history text that incorporated a large amount of geographic knowledge; it dealt in great and, more often than not, accurate detail with non-Islamic countries and peoples, as well as with Muslims and the lands of *Dar al-Islam*. In the eleventh century, the Andalusian geographer-historian (and both areas of inquiry were inextricably intertwined for most Muslim scholars who studied the cultural world) Abu Ubaydallah al-Bakri (ca. 1014–1094) confined his writing to Europe, Africa, and Southwest Asia, but what he wrote in his *Book of Routes and Realms* of circa 1067/1068 was first-rate. Although he stayed at home in Muslim Spain, he carefully collected eye-witness accounts from travelers, and his account of Ghana constitutes one of our most important sources of information for that West African trading kingdom.

Another Andalusian geographer, Abu Abdullah Muhammad al-Idrisi (1099–1165/1166), traveled throughout the Mediterranean and to portions of Christian Western Europe. He even served for eighteen years as scholar-in-residence at the court of the Christian king, Roger II of Sicily. His *Book of Pleasant Journeys into Far-away Lands* contained travel accounts of such distant lands as China that he garnered from the writings and reports of others. His map of Afro-Eurasia, which he produced in 1154 and which is known as the *Tabula Rogeriana* (*Roger's Map*), was accompanied by a detailed commentary known as the *Book of Roger*. In typical Islamic style, the map is oriented with south at the top and, as was also typical for Muslim maps, shows itself largely tied to the model established by the Greco-Roman geographer Claudius Ptolemy (ca. 90–ca. 168). Although a major improvement on earlier maps, it exaggerates the length and breadth of East Africa, extending it all the way to the Pacific by making it the southern coast of a greatly reduced Indian Ocean. It also shows an overlarge Arabian Peninsula dominating the northern reaches of the Indian Ocean, and it greatly reduces the size and, by implication, relative importance of the Indian sub-continent.

Its depictions of China and Southeast Asia, however, are quite good, considering their distance from Sicily. Apparently he had received not only detailed reports but maps from Muslim travelers to the Far East.

The *hajj* to Mecca gave birth to a specific genre of travelogue, *al-rihla fi talab al-ilm* (travel in search of knowledge). The greatest of all rihlas was, without a doubt, a work titled *A Gift to Those Who Contemplate the Wonders of Cities and the Marvels of Traveling*. The collaborative effort of a professional writer, Ibn Juzayy, and the greatest known traveler of his age, Ibn Battuta (1304–1369), the book details the latter's travels between 1325 and 1354, travels that stretched on a west-to-east axis from Islamic Spain and sub-Saharan West Africa to Southeast Asia and possibly southern China. (His muddy descriptions of China have raised doubts that he ever went that far east.) Inasmuch as a number of entries and sidebars deal with aspects of his travels, no more need be said here, except that rihlas such as this were copied and recopied many times over to feed the curiosity of a ready audience among literate Muslims.

Chinese descriptions of the world beyond the Middle Kingdom also proliferated after 1000 CE. Thanks to the availability of large amounts of cheap paper and a printing industry (unlike the Islamic and Christian cultures of the West, where manuscripts were laboriously copied by hand), Chinese geographers were able to disseminate their work to a fairly large reading clientele. Two of the more important descriptions of Afro-Eurasia were composed by Zhau Rugua in the mid-thirteenth century and Ma Huan in the early fifteenth century.

Zhau Rugua served as the Inspector of Foreign Trade at Quanzhou, China's most important port. Arab merchant-sailors knew the city as Zaitun, and Marco Polo, who characterized it as "one of the two greatest harbors in the world for commerce," called it Zayton. However it was known, Quanzhou was probably the busiest port in the world at this time, and it likely remained so through the early years of the Ming era. Very much a stay-at-home like al-Bakri, Zhau Rugua depended on the accounts of merchant-sailors who passed through his custom house and also was indebted to an earlier catalogue of

foreign lands, peoples, cultures, and products composed by Zhou Kufei in 1178. Regardless of Zhau's lack of first-hand knowledge, his *Description of Foreign Peoples* provided a growing reading public with accounts of life in such exotic lands as Arabia, Spain, and Borneo.

Ma Huan (ca. 1380–after 1451), author of *The Overall Survey of the Ocean's Shores*, was a Muslim Chinese who traveled into the Indian Ocean on the fourth (1413–1415), sixth (1421–1423), and seventh (1431–1433) voyages of Zheng He. His account of what he saw, experienced, and heard was printed as a book in 1451 (just about the same time that Gutenberg was printing his first Bible in Mainz) and served to bolster Chinese knowledge of this culturally complex oceanic ecumene, an area in which Chinese mariner-merchants had been quite active for several centuries before Admiral Zheng He's seven voyages.

In 1402, three years before Zheng He's first voyage into the Indian Ocean, a world map was produced in Korea. Officially known as the *Map of Integrated Regions and Terrains and of Historical Countries and Capitals* but more popularly called the *Kangnido*, it depicts Afro-Eurasia based on three apparent sources: earlier Chinese maps, Islamic maps, and information garnered as a consequence of the Mongol Peace. It is either the oldest or second oldest extant world map from East Asia, the other contender for the honor being the Chinese *Great Amalgamated Map (Da Ming Hun Yi Tu)*, which, although inferior, shares many features with the *Kangnido* and might date to as early as 1389. Whatever the case, the *Kangnido* correctly depicts the proper shape of Africa, unlike most Islamic maps that show the southern tip of Africa pointing east. China, Southeast Asia, and India are merged into one massive landmass that dominates most of the map, suggesting that, at this time, the Indo-Malay-Chinese nexus was the economic and cultural center of the world, so far as most East and South Asians were concerned. The map also, but in less dramatic fashion, exaggerates the size of the Arabian Peninsula, as well as that of the Korean Peninsula. The latter was a product of ethnic pride; the former was a consequence of Arab sources. Africa is under-sized, but that is not

surprising. What is surprising is its depiction of western Eurasia, including the Mediterranean and Black seas and Europe. They are not that clearly delineated, but they are there.

A quarter of a century earlier and half a world away, a Majorcan Jewish cartographer, Abraham Cresques, and probably at least one son, created for presentation to the king of France a map known today as the *Catalan World Atlas*. The map's accompanying text emphasizes the spherical nature of the world, a rather unexceptional position at the time inasmuch as John Holywood's *Regarding the Sphericity of the World*, which was based on a ninth-century astronomical text by al-Farghani, had been in wide circulation within Western Europe's learned circles since the early thirteenth century. Notes and pictures throughout the map also show that its makers were well acquainted with fourteenth-century Latin Europe's two most popular travel accounts, the real-life account of Marco Polo and the fictional, tongue-in-cheek account of "Sir John Mandeville" (which, however, was based on a number of real travelogues and scientific texts). What is more, its accurate depiction of the Mediterranean and Black seas and surrounding lands shows that the cartographer(s) used mariners' portolan charts, which showed in great detail the contours of coastlines and places of refuge and danger, that were being produced in Western Europe from at least the thirteenth century. As noted elsewhere, the map also provides an accurate depiction of Chinese mercantile traffic in India, and it delineates in gold color the Gold Road that crossed the Sahara. It even shows Mali's king, Mansa Musa, holding a huge golden nugget. Legendary and biblical characters also are there, such as Prester John, the Queen of Sheba, and the Three Magi, but it also delineates cities in China that Marco Polo and other Western adventurers described. It even has a picture of Emperor Khubilai Khan. Although it shows pygmies battling storks, a fiction that went back to Greek antiquity, it is devoid of any depictions of such fantastic humans as persons with eyes in their chests and dog-headed and two-headed people—all of which were soberly reported by Greco-Roman naturalists and passed on as supposed facts through Arab texts. Such

humans were still being described and depicted in various Western texts and drawings for more than a century after 1375, but they are not to be found here.

As with the *Kangnido* and the various geographies and travel accounts that grew in popularity over these five centuries, this map is a testament to a growing knowledge of the contours of Afro-Eurasia and its peoples.

—*Alfred J. Andrea*

Arab and Chinese Cartography

For many centuries prior to the rise of their empire in the seventh century, the Arabs had long participated in the widespread commercial activities in the Mediterranean and the Indian Ocean. Whereas the Parthians played the role of middleman along a number of the land routes of the great Silk Road that connected Han China and Rome, the Arabs traveled its sea routes along a commercial axis that ran from the northern reaches of the East African coast to coastal Southeast Asia. Given this wide-ranging commercial network, the Arabs accumulated a good deal of geographic knowledge regarding their expanding sphere. Together with the knowledge that they inherited from classical Greece and Rome, the Arabs possessed the most accurate information on Afro-Eurasian geography and made the best maps of that vast region by the twelfth century.

Commercial interests and war brought the Arabs into close contact with the Chinese, who had built their own empire on the eastern edge of Eurasia. After the Battle of the Talas River in 751, the Arabs curtailed Chinese influence in central Asia and became neighbors of the Tang empire, which by then was in decline. While Arab warriors craved glory, Arab merchants were attracted to China by profit. The southern Chinese city of Guangzhou was said to have thousands of Arab residents in the early tenth century, most of them merchants. Such contacts opened up channels for the dissemination of knowledge between these two cultures, including cartography.

The Chinese had developed an indigenous tradition of mapmaking based on a grid system,

which divided a geographic surface into different grids to allow location of a point on a map. The grid system not only reflected the particular (although misleading) Chinese worldview that China is the Middle Kingdom but also provided a tool to calculate distance and possibly a mathematical approach to mapmaking. From the tenth century onward, however, Arabic geographic knowledge began disseminating across the Chinese world and, in the process, greatly influenced Chinese cartography. Likewise, an increasing familiarity with the lands, waters, and peoples of East Asia aided Arab cartographers and geographers to craft better maps and geographic descriptions of this vast region.

Many individuals from the Arabic world contributed to Chinese cartography, but no one's contribution was greater than that of Rashid al-Din (1247–1318), a Persian of Jewish descent who, in 1295, served as vizier for Ghazan Khan of the Mongol Il-khanate. Taking advantage of his position, Rashid al-Din gained access to various government archives and ventured into the fields of calligraphy, translation, and historiography. His major work of history, *Collected Chronicles*, contains a geographic compendium titled “Suvar al-aqalim” (“Configuration of Climes”). The digest of this compendium, which is all that remains today, reveals that he had a fair understanding of the basic geography of East Asia, particularly China. For example, he mentioned 25 Chinese locations apparently previously unknown to outsiders and China's division into different provinces, and he confirmed that the Yuan court established a network of postal services that covered most of the empire. This in turn preserved important information regarding China's thirteenth-century road system. In compiling this work, Rashid al-Din took advantage of existing works commissioned by Mongol rulers up to that point. The Department of Foreign Envoys (*bui tong guan*) of Yuan China was established in 1277 to collect information about foreign geography, postal stations, pasturage, and regional products and to assemble vital strategic maps.

Chinese cartography in turn also benefited greatly from the transmission of geographical information from Western Asia. The Imperial Library Directorate of the Yuan government was

staffed in part by Muslim scholars and undertook the task of exchanging up-to-date scientific and scholarly information and ideas including geography and cartography. Jamal al-Din (1231–1316), a Persian astronomer, came to China during the reign of Mongke Khan. While Jamal al-Din's primary contribution was in the field of astronomy, he was also instrumental in the flow of geographic knowledge from the West to the East. One of the astronomical instruments that he brought to China, *kurab-i arz* (territorial globe), was a state-of-the-art illustration of the world. Made of wood, it was fashioned into a sphere, representing the globe; different colors were applied on various parts of this globe to show waters and lands. It was also marked with small squares used to calculate the breadth and length of countries and distances between places. Jamal al-Din was also responsible for preparing a massive geographic compendium at the court's order in 1285, which he completed in 1291 as the *Comprehensive Gazetteer of the Great (Yuan) (Da [Yuan] Yitong Zhi)*. Jamal al-Din, together with his Mongol supervisor and Chinese assistants, continued to work on the compendium in the decade that followed, and its final version came to about 1,000 chapters, with a scope that covered the entire Mongol empire.

While only fragments of this compendium are preserved today, its impact on Chinese cartography was tremendous. The next two centuries saw a blooming of cartographic works in China. Many Chinese geographers inherited information, ideas, perspective, and mapmaking methods from such Muslim scholars as Jamal al-Din and produced many volumes of cartographic books and illustrations of not only China and its neighbors but also of faraway lands.

Al-Jazari's Compendium of Science and Useful Practices in the Making of Mechanical Devices

The birth date, early life, and education of mechanical engineer Ibn al-Razzaz al-Jazari are unknown. Al-Jazari completed his book *Kitab fi ma'rifat al-hiyal al-handasiyya* (The Book of Knowledge of Ingenious Mechanical Devices) on January 16, 1206. An annotation by Muhammad ibn Yusuf ibn Uthman al-Haskafi, who made a

The Elephant Clock, from The Book of Knowledge of Ingenious Mechanical Devices by al-Jazari, 1206. (The Metropolitan Museum of Art/Art Resource, NY)

copy of the manuscript now in the Topkapi Sarayi Library in Istanbul, indicates that al-Jazari was no longer alive on April 10, 1206. Like his father, al-Jazari became a court engineer at the Artuqid dynasty's main palace in Diyar-Bakr in eastern Anatolia. He served three kings from the Artuqid dynasty of Oghuz Turks who ruled eastern Anatolia and northern Iraq. The Artuquids, vassals of Saladin and his Ayyubid successors, provided al-Jazari with peace, stability, and adequate funding for his experiments. During al-Jazari's time, Seljuk control of trade routes increased the need for improvements in agriculture and manufacturing, and intellectual exchange was also enhanced with the development of libraries, observatories, and schools.

His peers gave him the title *Badi al-Zaman*, or "Prodigy of the Age." During his lifetime, along with public works engineering al-Jazari created water and candle clocks, water pumps, ornamental fountains, and automated toys. An example of his automata is a mechanical boat with drinking men and musicians.

Al-Jazari portrayed himself as an engineer, not as an inventor, who improved through careful design and experimentation the work of others. None of his devices survives, but his illustrated book written in Arabic describes 50 of his devices. The invention of the piston pump and refinements to segmental gears, floats, and conical valves for clocks and automata are his major contributions. Donald R. Hill, historian, engineer, and translator of al-Jazari's book, concludes that al-Jazari was a careful artisan. Al-Jazari's descriptions of his valves and palace door cast from locally mined copper in closed mold boxes with green sand indicate that he had greater control than his predecessors had over the casting of these items.

As an engineer, al-Jazari solved practical problems such as lifting irrigation water from local rivers that had steep banks. He invented a pump that lifted water to a height of about 33 feet (10 meters). Such pumps operate by using pistons that open a valve that then allows a liquid to flow into a chamber. When the valve closes, the liquid discharges from the chamber. Al-Jazari's pump is significant because it utilized a double-acting principle, the conversion of rotary into

➤ WHERE CAN WE FIND AL-JAZARI TODAY?

Hand-colored pages from Al-Jazari's illustrated engineering manuscript, the *Book of Knowledge of Ingenious Mechanical Devices*, are at the Museum of Fine Arts in Boston, the Metropolitan Museum of Art in New York City, and the Louvre in Paris. The Bodleian Library at Oxford, the Hagia Sophia, and the Topkapi Sarayi Libraries in Istanbul possess the most complete copies of the original manuscript. Al-Jazari was unable to use mathematics or geometry to describe the workings of his creations, but he did provide detailed discussion and drawings that explain the appearance, purpose, and functioning of his devices. He explains how to manufacture, assemble, and fit together the component parts. Al-Jazari's instructions and drawings were so carefully executed that it was possible to exhibit at the 1976 World of Islam Festival in London working reconstructions of one of his water clocks, a water pump, and a phlebotomy (bloodletting) device. Working replicas of al-Jazari's colorfully decorated elephant clock can be seen at the Ibn Battuta Mall in Dubai and Le Locle, Switzerland.

—Fran Hassencahl

reciprocating motion and a reliance on suction pipes. Such pumps were later incorporated into steam engines. Although his water-driven wheel, a *saqiya* with tipping buckets, served only to entertain, it also could have been rescaled to lift water from deep wells.

His water clocks included decorated figures such as falcons, peacocks, humans, and models of the sun, moon, and planets. The figures moved, simulated playing musical instruments, and were part of the clocks' timekeeping mechanisms. Water clocks were prayer-time reminders and billing systems. Recipients of irrigation water paid for it in time units rather than by the volume of water received.

The World of John Mandeville

John Mandeville is the pen name of an unknown author who, around 1356 or 1357, wrote what he said was a true travel narrative based upon 34 years of experience in the Holy Land and Asia. Like *The Voyages of Marco Polo*, which appeared 50 years earlier, *The Book of John Mandeville* was popular and widely read. Appearing originally in French, by 1400 it had been translated into English, Dutch, German, Czech, Italian, Spanish, and Latin. Following the invention of the European printing press circa 1450, it became one of the most successful books of its kind, reaching over 60 printings by 1600.

By then, thanks to the achievements of the Age of Exploration, more accurate information about the East had been made available, and some scholars began to suspect that the book was a forgery. We now know that it is a compilation and reworking of earlier travel narratives such as William of Bodensale's *Book of Certain Overseas Regions* (1336) and Friar Odoric of Pordenone's *Journey* (1330). Instead of characterizing the work as a case of plagiarism, however, historians have come to understand that copying and rewriting parts of earlier works was a standard practice in medieval literary culture. Most now see *The Book of John Mandeville* as a particularly inventive dialogue with earlier texts and with contemporary intellectual and religious culture. As such, it reveals a great deal about the ways in which the *Mandeville* author and his readers viewed the world around them.

What interested them most were Egypt and the Holy Land. Even in the late fourteenth century, there was still much talk of crusading. Whether as conqueror or pilgrim, Western elites dreamed of visiting the places where Jesus and

his apostles had lived and where the stories of the Old Testament had occurred. To that end, *The Book of John Mandeville* satisfied the curiosity of actual and armchair travelers alike. As it was based upon dozens of firsthand accounts and scholarly treatises, the information provided was as accurate as one was likely to find in the late Middle Ages. It contained a list of the holy sites, directions on how to get to Jerusalem, a description of the beliefs and habits of the Muslims, a brief history of the region, and practical advice on where to buy supplies and how to avoid being swindled by diamond merchants and balm sellers.

To our modern way of thinking, some of the stories seem fantastic, such as the one about the wells that the young Jesus made with his feet while playing with other children near Cairo. Another story is about the phoenix, a bird that burned itself once every 500 years upon the Temple of Jerusalem in Heliopolis only to be reborn from the ashes. Yet people thought differently in the past, and for the most part it was not so much “Mandeville’s” accounts of the Holy Land that they found unbelievable but his tales of exotic Farther (Central and East) Asia, which appeared to them a strange and frightening place but also one filled with wonders and opportunities for enrichment.

In *Mandeville*, as in similar narratives, including those that the Mandeville-author copied, the farther away from Europe one ventured, the more confused the geography became. Readers would have gathered that somewhere east of Jerusalem, Arabia, and Persia, lay the lands of legend that few had seen: India, Cathay (China), the kingdom of Prester John, the Terrestrial Paradise, and innumerable and diverse islands that were home to monstrous races of human beings, grotesque beasts, powerful kings, odd customs, and always, everywhere in the wondrous East, great cities and great riches.

There was, to be sure, some useful information. The reader could learn, for example, how pepper was grown and harvested and about the laws and customs of the Mongols should anyone need to travel through their territory on the way to the court of the Great Khan. Even Christopher Columbus owned a copy of *Mandeville*, which he used to prepare for the westward voy-

ages by which he hoped to reach the spices and gold of the “Indies.” Columbus was particularly interested in what *Mandeville* had to say about the sphericity of the earth. It was common knowledge at the time, at least among the educated, that the world was round, but *Mandeville* claimed that it could be circumnavigated, that the seas and heavens encompassed the globe, and that once a ship had sailed to the other side, it would be able to return.

For those who enjoyed marvels and adventure stories, the fictitious traveler described the Hindu temples he had seen, his encounters with devils in the Enchanted Valley, the cannibals of the Isle of Lamary, and crocodiles, elephants, giraffes, white lions, geese with two heads, and sheep as large as horses. He told of Amazons, pygmies, and giants; dog-headed people; a tribe who ate serpents; and another that survived on nothing but the smell of apples. There was even an island where everyone went naked and where men and women had sex with whomever they pleased.

Surely some readers had their doubts, but the *Mandeville* author convincingly portrayed his narrator as a honest, humble, and pious knight, thereby lending much credence to his claims. As suggested above, it was not until much later, not until an era when men really could circumnavigate the globe, that some began to see *The Book of John Mandeville* for what it really was.

True or not, the lengthy narrative reveals much about the world in which it was created and not just on the level of geography and ethnography. It is also a valuable indicator of faith and morals. In this context it served as a sort of moral compass, a mirror if you will, that reflected for Latin Christians both their virtues and their sins.

Although many likely glossed over the various subtleties of the author’s wit and message, none would have missed the point about a region near the lands of Prester John where kings were elected not on the basis of their wealth but for their good manners and their rightful judgments. Nor could they fail to nod their heads while reading about the Isle of Bragman. The author described a place where there was no theft, no murder, no injustice, and no poverty; where the inhabitants, though they be pagans, lived soberly, chastely, and moderately, worshipping God

and eschewing earthly things; and where, as a result, they were granted peace, security, good health, and plenty to eat.

Such moral stands were common enough in the European Middle Ages, and they mark *Mandeville* as a product of its times. (So too does the strain of anti-Semitism that runs throughout.) What is new and different, however, and what marks it equally as belonging to an age in transition and, in a certain sense, as a harbinger of things to come are its toleration (for the most part) of other cultures and faiths, the belief in both the scientific and the moral benefits of travel, the tendency toward cultural relativism, the message of (nearly) universal salvation, its use of a fictional narrator, and, most important of all, its enormous popularity.

The World of Ibn Majid

Ahmed Ibn Majid was an accomplished fifteenth-century Indian Ocean pilot (*muallim*) and the author of perhaps 40 poetic and prose works on navigation, thus ensuring his reputation as Islam’s greatest maritime geographer-cartographer. Such writings, however, were already part of a venerable tradition in the Indian Ocean, and he sketches an outline of his antecedents in his most famous work, *The Book of Profitable Things Concerning the First Principles of Navigation* (in Arabic, *Kitab al-Fawaid fi Usul al-Bahr wal-Qawaid*). Ibn Majid’s oldest-named predecessor is a pilot named Khawashir b. Yusuf who sailed for an Indian ship owner around 1000 CE and wrote navigational treatises based on firsthand experience and observation. (Earlier, the tenth-century Arabic geographer al-Muqaddasi described “navigation instructions which they [Indian Ocean

➤ PILGRIMAGE AND NAVIGATION

Because of the obligation of Muslims to make a pilgrimage to Mecca at least once if it is in their power to do so, the Red Sea was a crucial if treacherous thoroughfare for people and goods alike. Here Ibn Majid discusses some of the difficulties.

“We have mentioned in our *rajaz* [‘the rhythm of the camel’] poem *al-Sabiya* all the measurements which are needed on this coast [al-Sabiya] and have not left out a thing. My father also mentioned them with five different routes: the open sea route, the Arab and Sudani coastal routes, and the routes among the islands and he did not omit an island or a reef. With all this he brought his poem to an end and said in it the following:

The paper and the ink have been expended,
And I have not reached some numbers of the ten.

For the Sea of Qulzum al-Arab is the most dangerous of all the seas of the world and yet people use it more than all the seas of the world because of the ‘Ancient House’ [the Kaaba at Mecca] and the pilgrimage of the Prophet and because of the means of subsistence and the going and coming of food.”

pilots] study carefully together and on which they rely completely proceeding according to what is in them.”) Khawashir b. Yusuf was apparently the source for a now-lost work that Ibn Majid attributed to the celebrated “Three Lions,” the twelfth-century geographers Muhammad b. Shadhan, Sahl b. Abban, and Layth b. Kahlan. Despite their fame, Ibn Majid disparaged the trio for being “only compilers and not genuine authors, [who] never rode the sea,” and he claims that “there is in a single sheet” of his work “more value as to language, accuracy, usefulness, guidance, and advice than in most of what they have

composed.” Yet their renown was such that he proudly refers to himself as the fourth lion, the “Lion of the Sea.” In addition, Ibn Majid drew on the work of his father and grandfather, both of whom were experienced Red Sea pilots.

The Book of Profitable Things is the product of a mature student of navigation, yet much of its information had appeared previously in Ibn Majid’s poetic works, notably “The Gathering of the Summarizing Concerning the First Principles of the Knowledge of the Seas,” known simply as the *Hawiya* and written about 1462. Completed in 1489–1490 and running to about 200 pages, *The Book of Profitable Things* covers a host of topics to be mastered by the *muallim*, together with specific directions about how to get from one place to another. The most technically demanding of these concerns celestial navigation: lunar mansions (the 28 areas of the sky through which the moon passes in the course of a month), measuring east-west distances, calculating the altitude of the Pole Star (*bashiyat*), determining latitude by measuring the altitude of stars (*qi-yas*), and the revolutions of the sun and the moon. Of a more general nature is direction-finding at sea: determining the 32 compass rhumbs; routes between ports; how to read the sea, wind currents, and presence of sea creatures and the like to find land (*isharat*); the nature of the monsoon winds; and the seasons of the sea. Final topics include the running of the ship and the subject of shipboard politics and crew management (*siyasat*).

Although he claimed that he would “write about all of [a ship’s possible] defects for few people have done so in the present time,” Ibn Majid referred only in passing to Indian Ocean ship construction and rigging, subjects about which modern researchers would like to know more, including the use of the compass and the shape of the sails. In his recommendations for how a shipmaster ought to conduct himself with his crew and passengers, he stressed that one must be firm but fair with the former while treating passengers with respect: “Listen to everything they say, accepting anything good and rejecting the bad. Be firm and strong when speaking to them but pleasant.” Never take sides in an argument, he cautions, and “Do not notice a disorder in the ship, and ignore it until a later date, except

when absolutely necessary, for it will only get out of hand.” The pilot must also be vigilant about the ship and its integrity, “especially the rudder.” Most important, because it affects everything else, the pilot must know when and how much to sleep. “When you are tired do not let it get the better of you, for it induces forgetfulness, but do not sleep except the amount required of you by old age or the extent of your tiredness, and when you sleep do not leave the helmsman alone.” Elsewhere he observed: “I have written this book only after 50 years have passed me by [as a navigator?] and during that time I never left the helmsman alone without standing over him or my deputy in my place.”

Ibn Majid’s primary geographic focus was on the western Indian Ocean, including the Red Sea below Jeddah (the port of Mecca to which Indian Ocean pilgrims sailed for the hajj); he did not discuss the Persian Gulf, where commerce had declined in the fifteenth century. He displayed vastly more familiarity with the southern coast of the Arabian Peninsula (from Aden to Oman), East Africa and Madagascar, and especially western India and the Laccadive and Maldiv Islands, which were important way stations for sailors sailing between Southeast Asia and Southwest Asia or East Africa. His calculations for the latitude of various ports on the east (Coromandel) coast of India and the Bay of Bengal coast of Southeast Asia are also accurate. Although Melaka (Malacca) was at the height of its prosperity in the fifteenth century—its decline would set in after the Portuguese captured the port in 1511—merchants from Gujarat in northwestern India dominated the trade there and beyond, and Ibn Majid, who was probably from Oman, is less familiar with the geography

of the archipelagos of Southeast Asia or the China Seas.

Ibn Majid is believed to have died sometime shortly after 1500, only a few years after Vasco da Gama opened the direct sea route from Atlantic Europe to the Indian Ocean. A mid-sixteenth-century Yemeni historian identified Ibn Majid (possibly out of spite) as the man who piloted Vasco da Gama’s ships from Malindi to Calicut, a passage with enormous repercussions for Eurasian and world trade. Recent historians dismiss the claim because Portuguese sources uniformly refer to Gama’s pilot as a Gujarati and because Ibn Majid would certainly have anticipated the profound implications of the Portuguese presence in the Indian Ocean, which he expounds on in his late poem *al-Sofaliya*.

■ Introduction: Diffusion vis-à-vis Independent Invention

One of the longest-standing debates in the history of technology is between those historians who emphasize how technological innovations are rooted in the time and place in which they occur, arguing that the same devices and processes are “independently

invented” in different places, and “diffusionists” who see technical innovations as spread from culture to culture. The role of medieval Chinese technology in the Middle Ages is a classic area for debate. Medieval China was in many ways the most technologically advanced civilization

on earth. Chinese inventions include paper as well as the “big three” technologies that the seventeenth-century English philosopher Francis Bacon would later point to as the dividers between the ancient and the modern world: gunpowder, the magnetic compass, and the printing press. These inventions later emerged in other areas of Eurasia, leaving the question of whether they were independently invented or whether Chinese technology spread westward.

There are some cases where a technology’s diffusion from China can be clearly traced, as in paper’s spread to the Islamic world and eventually Christian Europe. Other cases of the diffusion of Chinese technology are more mysterious. The principle of using a magnetic needle to find direction was invented by the Chinese but was refined and improved by Mediterranean sailors to the point where some historians claim that it was an independent invention. Why did printing spread from China through eastern Asia to Korea and Japan and then jump thousands of miles to appear in Germany? It seems obvious that a Chinese printing press could not have traveled the long distance from China, nor is there any evidence of such a device, but could Gutenberg have been aware of East Asian printing and attempted to imitate it? There is no certain answer to this question.

Certain settings were particularly suited to technological diffusion, such as maritime trade. North European shipbuilders adopted the Mediterranean triangular, or lateen sail, although the lateen sail was independently invented by South Pacific shipbuilders. War was another area where different cultures came into contact and exchanged technologies. There is a long military tradition of learning from one’s enemies, and the diffusion of military techniques and devices can also sometimes be traced. (Military techniques could also be held tightly secret to ensure their possessor’s advantages. The exact formula of the Greek fire of the Byzantine empire, a devastating flame weapon used in naval battles, was a closely guarded state secret and remains unknown to this day.)

The creation of large areas of relative peace and open trade could also facilitate technological transfer. The Mongol empire seems to have

been the means by which Chinese knowledge of gunpowder arrived in Europe and the Middle East, although the exact steps remain unknown, and some have claimed that gunpowder was independently invented in Europe.

There are also different types of diffusion. Technological devices can spread as actual objects or as ideas, as papermaking skills enabled Chinese workers to establish paper mills in the Islamic world. The importance of maintaining control of lucrative or deadly technologies often led medieval and early modern states to forbid the emigration of artisans with knowledge of unique technologies.

—William E. Burns

The Spread of Paper to Europe after 1000 CE

After its first attested use in the Chinese Han empire around the late second century BCE, paper and papermaking gradually spread in a westward direction, following the routes of Buddhist monks and merchants traveling along the Silk Road. Contrary to a legend that ascribes the introduction of paper into western Asia to Chinese prisoners captured by Muslim armies at the Battle of Talas (751), by the seventh century and well before the expansion of the Islamic world paper was used throughout the Central Asian oasis cities for writing and other purposes. The unification of western Asia and later the integration of Central Asia under the Umayyad and Abbasid dynasties expedited and expanded the use of paper across the Islamic world. From its western reaches in the eastern Mediterranean and North Africa, paper and papermaking were introduced to the European continent from the tenth century onward. In the Islamic world and in Christian Europe the use of paper effected lasting changes in the transmission of knowledge and in record keeping, business, and daily life.

By the late eighth century the Abbasid government in Baghdad was making extensive use of paper for tax records and landholding and army registers. The various government offices in the city relied on paper produced locally. In 794–795 the first paper mill in Baghdad was established. During the next several centuries the

➤ FABRIANO PAPER

Even though paper was first introduced elsewhere in Europe, Fabriano today enjoys the reputation of the oldest paper-producing town in Europe. Papermaking started there as early as the 1260s, and paper is still today manufactured according to centuries-old procedures. The medieval commercial success of Fabriano paper can be attributed to its technical advantages as well as the acumen of medieval Italian merchants. In contrast to Chinese papermakers who initiated the use of vegetable starches to improve paper quality, the Fabriano papermakers used animal gelatin to make their products stronger. This technical improvement proved very significant in popularizing paper among European writers who were used to working with the stiff quill pen, which wrote well on parchment but often proved too sharp and hard for the softer paper. Also in the thirteenth century, Fabriano papermakers began to identify their papers through watermarks. The watermarks were the result of patterns woven into the screens that were made out of metal wires. Watermarks may have been a spillover from the dominant manufacturing sector in Fabriano: wool manufacturers impressed similar marks on their products as trademarks. Between the thirteenth and fourteenth centuries, Italian merchants carried Fabriano paper in large quantities across long distances, selling it

Fabriano paper mill, from Novum Italiae Theatrum, 1724. (Dard Hunter, The History and Technique of an Ancient Craft, 1974)

in different qualities and, in the case of the lower-quality products, at below-market prices. Such marketing strategies resulted in the decline of the competitiveness of Spanish and Syrian paper and led to the further development of paper manufacturing in Fabriano in subsequent centuries.

—Hilde De Weerd

papermaking industry expanded to such an extent that a special market, the Stationers' Market, hosted over 100 stalls selling paper products. Immediately afterward paper mills, processing rags from urban populations, appeared in other parts of the Abbasid empire, such as the Syrian cities of Tripoli, Manbij, and Damascus. Merchants sold Syrian paper in Egypt by the ninth century. Manufacturing took off on the Egyptian coast from the tenth century onward. In contrast to Egyptian consumers, North African scribes working in the region corresponding to present-day Tunisia continued to rely on parchment in the first centuries after the introduction of paper. The parchment was made from sheepskin that was widely available locally. To a lesser extent they wrote on paper imported from Egypt.

It was most likely that this same paper was first used in the Iberian Peninsula.

By the middle of the tenth century, paper was available in Muslim Spain. Early descriptions of the use of paper there refer to the scholarly use of paper. Even though religious, legal, literary, and scientific knowledge was commonly transmitted through oral traditions in the Islamic world, the arrival of paper resulted in the large-scale recording of knowledge in writing, although written records were still frequently considered as supplementary aids, secondary to and not as reliable as oral testimony. The use of paper for the preservation and transmission of knowledge easily crossed religious and cultural boundaries, as Iberian scribes began to copy Christian texts on paper from the tenth century onward. The

earliest known European Christian manuscript on paper, the Mozarabic Breviary and Missal preserved in the Benedictine Abbey of Santo Domingo de Silos in northern Spain, dates to the second half of the tenth century.

As in most Islamic lands, the importation of paper into Spain was soon followed by local production. Paper mills appeared in the eleventh century, and during the following centuries merchants traded Spanish paper throughout the Mediterranean.

Paper was first used in Sicilian official documents dating to the late eleventh century. After half a century it became a commonly used material in commercial and legal transactions in northern and central Italy. Notaries at the time used paper imported from Spain. Local production began in the early thirteenth century, first near Genoa and shortly afterward in Fabriano, a town in central Italy where paper is still manufactured today. Paper from Fabriano, whose similarities with Syrian paper suggest that the Italian papermakers' skills were influenced by direct contact with the eastern Mediterranean during the crusades, gained the upper hand in the international paper market by the fourteenth century due to the Italian merchants' superior marketing techniques. In the fourteenth and fifteenth centuries paper mills were established throughout Western Europe and thus laid the foundation for the revolutionary impact of the printing press after the mid-fifteenth century.

Adapting the Technology of Warfare

Some of the most efficient and deadly technology used by medieval European armies originated in Asia. Middle Eastern peoples had long been aware of and made use of military innovations from the Far East, especially China. Consequently,

the transfer of such technology to the West was the result of European interaction with Eastern Christians, Arabs, Turks, and Mongols. While the transfer of military technology from east to west had begun at least as early as Greek antiquity, it continued throughout Europe's early Middle Ages (ca. 500–1000 CE) and reached its peak during the time of early European expansion (roughly 1100–1500). Among the most important Eastern military weapons to make their way to Europe were the crossbow, the trebuchet, and gunpowder.

The common crossbow originated in China and became a standard infantry weapon in its military forces at least as early as the fourth century BCE. There is some evidence that the ancient Greeks also used a primitive type of crossbow during the same period, but it did not experience the same type of widespread use and development that took place in China and beyond in the centuries that followed. Crossbows were not commonly used by west European armies until the beginning of the ninth century, at a time when they were much better developed both in function and accuracy. East-West interaction contributed to the development of better crossbows. One example is that during the crusades, Europeans adapted the much stronger materials of the so-called Saracen composite bow (wood, horn, and sinew that were glued and bound with animal tendon) to the construction of crossbows. This Saracen bow was itself a creation of the central Asian steppes and had been brought into the Middle East by various nomadic peoples, such as the Turks. The trigger of the crossbow also experienced considerable development in Europe. Although bronze triggers with safety notches had been in use in China since around 200 BCE, more sophisticated iron triggers were developed in late medieval Europe, where even Leonardo da Vinci took an interest in their development.

No siege weapon in medieval Europe was as destructive or as terrifying as the counterweight trebuchet. Its superior accuracy allowed for its use in targeting and wearing down a specific section of a defending city's wall. The trebuchet employed a sling action that was driven by a counterweight, either by human counterweight or heavy stones. Its superior power allowed for

hurling larger projectiles against or over city walls from great distances. In recent experiments, a trebuchet having a 441-pound (200-kilogram) counterweight threw a 33-pound (15-kilogram) ball 590 feet (180 meters) and a 104-pound (47-kilogram) ball 328 feet (100 meters), all within a target area of only 65 square feet (6 square meters). Because of their enormous size, trebuchets were usually built at the siege site using local materials.

The trebuchet was a product of ancient Chinese military innovation that was improved technologically and used extensively by early Islamic and Byzantine armies but was only brought to its fullest development in later medieval Europe (thirteenth to fifteenth centuries). In a sense, the later trebuchet was the collective achievement of Chinese, Islamic, Byzantine, and European societies and illustrates the transfer of technology that took place across Eurasia during the Middle Ages.

No technology contributed as much to the end of Europe's traditional forms of warfare as gunpowder. Gunpowder is a substance that burns rapidly, releasing gases that act as a propellant in firearms. Firearms and cannons ultimately made both the armored and mounted knight, as well as many castle fortifications, obsolete.

Although gunpowder appears in Chinese sources as early as the second century CE, the Chinese did not use it in warfare until the early tenth century (first as incendiary weapons and later as grenades). The first known use of gunpowder as a propellant came in the twelfth century when the Chinese developed mortars, first using bamboo tubes and then various types of metal tubes in the thirteenth century. Chinese advances with gunpowder came around the time that the Mongols were conquering China, ensuring that they were among the first to have access to the new technology. Consequently, the Mongols adopted and even improved upon the Chinese gunpowder-propelled artillery and mines for use during their westward expansion into Islamic lands. As a result, in the mid-thirteenth century Islamic peoples acquired knowledge of gunpowder and its use in fireworks and rockets and were likely responsible for the transmission of gunpowder-propelled weapons to the West during a period of extensive military and

➤ DUELING TREBUCHETS AT THE SIEGE OF ACRE, 1191

The following account of the crusaders' siege of Acre in the summer of 1191, from the contemporary Third Crusade account known as *Itinerarium Peregrinorum et Gesta Regis Ricardi* (*The Pilgrims' Journey and Deeds of King Richard*), details the destructive effects of 11 trebuchets deployed against a defensive site known as the Maledicta (Curse Word) Tower and its adjacent walls. Of particular interest is the duel that took place between a crusader crew manning a trebuchet named "Bad Neighbor" and a Muslim crew manning a trebuchet called "Bad Relation."

"The king of France [Philip II] . . . concentrated on constructing siege machines and placing trebuchets in suitable places. He arranged for these to shoot continually day and night. He had one excellent one which they called 'Bad Neighbor.' The Turks [more likely Arabs] in the city had another which they called 'Bad Relation' and often used to smash 'Bad Neighbor' with its violent shots. The king kept rebuilding it until its continual bombardment partly destroyed the main city wall. . . .

Besides these, there was a trebuchet that had been constructed at general expense, which they called 'God's Stone Thrower.' A priest, a man of great probity, always stood next to it preaching and collecting money for its continual repair and for hiring people to gather the stones for its ammunition. This machine at last demolished the wall next to the Cursed Tower. . . .

King Richard's [King Richard I of England] trebuchets hurled constantly by day and night. It can be firmly stated that one of them killed twelve men with a single stone. That stone was sent for Saladin to see, with messengers who said that the diabolical king of England had brought from Messina, a city he had captured, sea flint and the smoothest stones to punish the Saracens. Nothing could withstand their blows; everything was crushed or reduced to dust."

The Compass

Although evidence that the Chinese were aware of and used magnetism in geomancy (*feng shui*) at least as early as the Han dynasty (202 BCE–229 CE), the oldest unambiguous description of a magnetized needle is Chinese and dates only from 1088, and the first accounts of navigational

compasses appeared, also in China, in the twelfth century. By the 1300s the Chinese were producing "seaway compass charts" that included "terrestrial seaways" showing compass courses and distances. The earliest written evidence for the use of a magnetized needle for navigation comes from a late-twelfth-century work by the English scholar Alexander Neckham, who wrote that sailors touched a magnet with a needle "which is whirled round in a circle until, when its motion ceases, its point looks to the north."

Whether knowledge of the compass spread westward from China cannot be determined absolutely, but even if the rudiments of the compass originated elsewhere, the refinements that led to the practical navigational compass developed independently in the West. The Chinese wet compass consisted of a needle floating in a bowl. The so-called dry-card compass devised by navigators in the Mediterranean and western Europe in the thirteenth century was mounted on a pivot and calibrated to a compass card. This type of compass was adopted in Asia only after its introduction by European mariners in the sixteenth century. Another reason to consider the Western compass as an independent development is that the earliest reference to a compass in Arabic or Persian sources relating to navigation in the Indian Ocean dates to 1232, half a century after Neckham described it with such familiarity.

In the West, the needle and stone (lodestone, or magnetite) were used originally to locate the North Star, also called Polaris ("the Pole Star"), Stella Maris ("star of the sea"), and the Lodestar. In addition to helping with shipboard navigation, the compass revolutionized Mediterranean cartographers' development of sea charts, or Portolans. The Italian *portolano* originally referred to a collection of written sailing instructions, the oldest of which dates to 1296. Accompanying maps delineated the Mediterranean coast with remarkable fidelity and incorporated a bewildering array of compass roses, each with radiating rhumb lines showing sailing courses that extended to the edges of the map. How the use of the compass contributed to the accuracy of the earliest such charts is unclear.

Navigators had to overcome three major hurdles in particular with respect to the compass.

➤ FROM WIND ROSE TO COMPASS ROSE

Although people originally believed that the magnetic needle pointed to the North Star, the compass was developed not by astronomers but rather by mariners. Astronomers began dividing the circle into 360 degrees in antiquity, but medieval sailors sailed "by the wind" and thought in terms of 8 winds: north, northeast, east, southeast, and so on. The compass called for more discrete measurements, and these winds were divided into 8 "half winds" (north-northeast, east-northeast, etc.) and 16 "quarter winds" (north by east, northeast by north, etc.). This explains why the mariner's "compass rose" (named after the wind rose) is divided into 32 points of 11.25 degrees.

—Lincoln Paine

The first was an understanding of the magnetic north pole, which does not correspond with the geographic North Pole. The location of the magnetic pole varies over time, and its magnetic attraction varies in intensity from place to place. The angle of difference between the line to the geographic north and magnetic north is called magnetic variation. Between 1698 and 1700 English astronomer Edmund Halley spent 19 months at sea making observations intended “to improve the knowledge of the Longitude and the [magnetic] variations of the Compass.” The result was the first chart to show magnetic variation—shown as lines of equal deviation—published in 1701. These lines have to be updated continuously. A related problem was how to compensate for the magnetic attraction of iron fittings, guns, and eventually hull plating on the magnetic needle, which could be solved by the use of iron bars or other adjustable fittings or complex tables of deviation. The dry-card compass remained the standard type through the late 1800s, but it reacted too slowly to be practical in small fast vessels or in rough conditions. It was superseded by a compass suspended in a liquid solution beneath a glass dome. In such a design the compass card remains flat and properly oriented no matter the angle of heel, while the glass magnifies the compass card, which makes it easier to read.

Chinese Printing—Technological Innovations and Their Cultural Implications

The printing of Chinese language texts dates back to the seventh or eighth century. In the first few centuries after its invention, printing was largely limited to government offices, Buddhist and Daoist temples, and religious practitioners. Scholars and officials continued to rely almost exclusively on hand-copied editions of the classics, histories, and the literary works of past and contemporary authors. This situation changed dramatically during the eleventh and twelfth centuries. These centuries were marked by the expansion of commercial printing, the diversification of the types of texts in print, the adoption of Chinese printing technology to publish in a variety of non-Chinese languages, and experimentation with new printing technologies.

Woodblock printing, which was the method used for the earliest printed texts, remained the dominant technology in the mechanical reproduction of Chinese language texts throughout the imperial period until the late nineteenth century. From the eleventh century onward, Chinese printers also used movable type, which became the dominant printing method in Europe from the mid-fifteenth century onward. The earliest account of movable-type printing dates to the late eleventh century, when Shen Gua (1031–1095) compiled a notebook with his observations on scientific, engineering, and technological topics. He wrote that in the early 1040s a commoner called Bi Sheng (ca. 990–1051) preferred to print with ceramic movable type because this method allowed for cleaner and crisper copies and proved especially efficient in the fast reproduction of large numbers of copies.

Bi Sheng designed types for individual characters in clay, baked them, and then arranged the finished types in wooden cases according to the rhyme group to which the characters belonged. This method of arrangement was also used in character dictionaries at the time. When

► COMMERCIAL ENCYCLOPEDIAS IN CHINA

The Chinese concept of the category book (*leishu*, commonly translated as “encyclopedia”) first emerged in the eleventh century even though Chinese scholars typically dated the first encyclopedias to the period between the third and the sixth centuries. The crystallization of the new concept and Chinese scholars’ adoption of it expressed the expanded production and distribution of encyclopedias starting during the Tang dynasty (618–907) and accelerating in Song times. The increase in encyclopedias coincided with a gradual shift from the court as the center of their compilation to commercial print shops in the provinces as the primary producers and distributors. According to Yue Ke (1183–1240), “Bookstores in Jianyang are compiling them every day and printing them every month. They keep changing them in the hope of selling them quickly. They are traded and studied everywhere.” The production of encyclopedias in Song times was therefore intertwined with the development of commercial printing.

Commercial printing and the production of encyclopedias developed within the context of the civil service examinations. One example of such printed matter is Lin Jiong’s *Ultimate Essays on Origins and Developments from the Past to the Present—Newly Annotated for Examination Success*, published in three series and completed by the late 1220s or early 1230s. Its major subject areas (military organization, financial and fiscal affairs, the civil service, and educational institutions) reflected the material covered in the compiler’s examination preparation classes. Each entry consisted of one full essay, with primary source texts quoted in small font in the main text.

—Hilde De Weerd

working on a print job, he covered an iron plate with pine resin, wax, and paper ashes; placed an iron grid onto the iron plate; and then pressed the ceramic types into the grid. After sufficient copies had been printed from the form, he heated the plate so that the wax mixture melted, loosening the types and the grid. After cleaning, the types were ready for reuse. In the ensuing centuries and up to the fifteenth century, Chinese

printers continued to experiment with movable type, designing types in wood, tin, and bronze.

Despite the advances made in movable type printing, the majority of the Chinese printers opted for woodblock technology, as it required less financial risk. Because the Chinese written language uses around 50,000 characters, the number of types needed to print characters in differing font sizes required a large initial investment. The cost for preparing movable type was also higher because movable type necessitated the employment of literate typesetters and investment in a sufficiently large run of printed copies. Woodblock printers used the relatively cheap labor of often illiterate engravers and produced smaller initial runs, printing copies according to market demand.

The dependence of the efficiency of woodblock and movable type on language is also evident from the varied uses of print technology among central Asian peoples. The Uighurs, living to the west of the Chinese empire, first adopted woodblock technology but by the twelfth and thirteenth centuries shifted to movable type, as the latter was particularly suited to their alphabetic written language.

Woodblock printing proved to be a highly efficient method for duplicating Chinese texts and was a flexible medium open to new techniques for producing expensive high-end or cheaper low-end books and images. Multicolor printing, for example, developed during the early twelfth century. It was first applied in the printing of New Year pictures that decorated the homes of elites and commoners alike. In the fourteenth and fifteenth centuries printers also applied multicolor printing techniques to the reproduction of texts, especially to distinguish original text from commentary.

The development of printing techniques was accompanied by drastic changes in the uses to which print technology was put. The tenth and eleventh centuries were marked by the expansion of government printing. The emperors of the Song dynasty (960–1279) continued and expanded support for court printing activities begun under the preceding Five Dynasties period (907–960). The Song Directorate of Education, the central agency in charge of educational policy,

A Chinese alchemist of the eleventh century, Bi Sheng, is credited with creating movable-type ceramic blocks. (Bettmann/Corbis)

produced the largest number of books printed by the central government. Its publication record exceeded, according to one conservative estimate, 200 titles. In addition to the classics and classical commentaries, the directorate printed large numbers of historical and medical books. Its repertoire also included smaller numbers of encyclopedias, literary anthologies, Daoist works, and titles on law, agriculture, astronomy, geomancy, mathematics, and the military arts. The directorate printed large sets, such as dynastic histories, and complete editions of the classics and thus produced authoritative editions of texts that were considered essential for effective government. Apart from publishing books, government offices also used print technology for the duplication of calendars, forms such as certificates and civil service examination questions, and the production of paper money. Since taxes were paid in paper money, the use of printed paper currency alone ensured that the vast majority of the population was exposed to print.

Directorate titles were either donated or sold to officials and local schools. The boundaries between government and commercial printers were blurry. Government offices and officials regularly used government resources to print works that were sold to increase revenue or for personal profit. The directorate was a dominant force in the book market throughout the eleventh century but was gradually overshadowed by local government printers and especially independent commercial printers in the twelfth century. The expansion of commercial printing is apparent when we compare the number of locations with printing workshops before and after the withdrawal of the Song court to South China in 1126/1127. According to one estimate, there were around 30 printing centers during the Northern Song period (960–1126) as opposed to 200 in the much smaller territory of the Southern Song period (1127–1279).

Commercial printers published the same types of books as the directorate and also marketed a variety of literary works such as the collected works of individual authors and stories. The printing of stories and, later during the Yuan dynasty (1279–1368), of illustrated fiction as well as of a large body of useful manuals reflects the growing commercialization of the Chinese printing industry, which sought to satisfy the tastes of urban elites during these centuries. Studies of two of the most prominent commercial printing centers, the Southern Song capital city of Hangzhou and Jianyang Prefecture in the southeast, demonstrate that commercial printers also capitalized on the expanding numbers of students preparing for the civil service examinations and the increasing competitiveness of the examination process.

The number of candidates attempting the qualifying prefectural examinations increased from an estimated 20,000 in the early eleventh century to 400,000 by the mid-thirteenth century. This trend put tremendous pressure on the network of official schools that had been rebuilt and expanded during the early Song period. The official schools were unable to absorb the vast majority of students. Students turned increasingly to private and clan schools and relied on relatively cheap examination manuals put out by the print shops.

The central government attempted to regulate the expanding output of commercial printers through the issuing of publishing prohibitions on materials deemed sensitive as well as through prepublication review. Commercial printers also sought to protect their investments through copyright certificates that were occasionally issued by local government offices. Like other sectors in the Chinese economy, commercial printing went through a general decline in the late fourteenth and early fifteenth centuries. It was not until the Chinese economy recovered in the sixteenth and seventeenth centuries that Chinese society was ready for a second printing boom.

Korean Printing to 1500 CE

Just as the cultural unification of large parts of Asia under Islam facilitated the spread of paper between the seventh and tenth centuries, interactions among Chinese, Korean, and Japanese Buddhists in China's Tang empire (618–907), Korea's Silla kingdom (668–935), and Japan's Nara (710–794) and Heian (794–ca. 1180) eras ensured the smooth and fast transfer of printing technology in East Asia. The discovery of the earliest extant example in the world of a printed text in the Pulguk Temple (Kyongju, Korea) in 1966 illustrates both the importance of Korean printing in world history and the principal role of Buddhism in the early history of printing. The later history of Korean printing with earthenware, wooden, and metal movable type, several centuries before Gutenberg's mid-fifteenth century use of the movable-type printing press, underscores the role of successive Korean governments in promoting the use of movable type for the production of scholarly materials for literate elites.

Historians disagree on the question of whether Chinese or Koreans first mastered printing technology. Based on printed remnants of the *Vimala Nirbhava Sutra*, a Buddhist charm, or *dharani*, enclosed in the Sakyamuni Pagoda at the Pulguk Temple sometime between 705 and 751, Korean historians have argued that printing originated on the Korean Peninsula. According to Timothy Barrett, the sutra discovered in Korea may go back to an earlier edition of the same text printed at the Tang court and sent to the Korean court in 706, shortly after the death of Tang empress Wu (r. 690–705). Regardless of where one places the origins of printing, the order to print millions of copies of the same dharani by the Japanese empress Shotoku (r. 764–770) and the discovery of similar printed charms in Tang dynasty tombs suggest that printing spread across East Asia in the eighth and ninth centuries and was mainly used to reproduce Buddhist texts. Lay Buddhists invested in the printing of religious texts because they believed that their reproduction generated karma, or merit, for the individual producing and distributing them, which would ultimately ensure escape from the pain of rebirth.

The Buddhist investment in printing grew in subsequent centuries. During the eighth and ninth centuries, printing projects were typically restricted to short texts and individual titles. Larger projects took shape in the tenth century. The entire Buddhist canon was printed between 971 and 983 in China, and the Song court granted a copy to the Korean court. Between 1011 and 1082 Korean artisans carved and printed a new edition. After the woodblocks were destroyed during the Mongol invasion of 1231, work began in 1237 on a new and expanded version, known today as the *Tripitaka Koreana*. This edition's 81,258 woodblocks were carved on both sides and were finished by 1251. They are still in storage, virtually intact, at the Haein Temple in Kyongsang-nam (South Korea).

The eighth-century dharani, the Buddhist canon, and other historical and literary titles produced in the first centuries after the introduction of printing were printed with woodblocks. Woodblock printing was the oldest and dominant method for printing in pre-nineteenth-century East Asia. From the thirteenth century onward,

► THE INVENTION OF METAL TYPE

The use of metal movable type for printing texts is apparently first attested in a thirteenth-century statement that a book on rituals was printed with “cast characters” around 1234 on Kanghwa, an island off the west coast of the Korean Peninsula, that served as a temporary abode for the Koryŏ (918–1392) court then fleeing from the invading Mongols. Not every historian accepts this reference as unambiguous evidence of metal movable type that early. Indeed, the first extant examples of books printed with metal type date to the early fifteenth century. However, the use of coin casting technology by the early twelfth century and apparent references to movable type in thirteenth- and fourteenth-century Korean sources suggest that metal movable type was invented between the twelfth and fourteenth centuries.

Early Korean type was cast by sand-mold casting. This technique was first developed in China for the casting of coins and was imported to the Korean Peninsula in 1102. Wooden types were first impressed in wet sand, creating a mold. Upon the removal of the wooden types, artisans poured hot molten metal into the mold. If the artisans took great care in removing the wooden types from the sand, the resulting metal types, made typically of copper alloys, were exact copies of the carved wooden originals. Wealthier East Asian printers working with movable type preferred metal types over their wooden equivalents be-

Casts of Korean bronze type, 1406. (SSPL/The Image Works)

cause wooden type tended to break more easily and often produced lower-quality images. Apart from the preexistence of this casting technique, the development of movable type printing in Korea also benefited from the existence of established paper and ink manufacturing. Already in Tang times (618–907), Korean paper was imported into China and from that time onward gained a reputation for its high quality. When the Yi court launched its large-scale type casting and printing activities in the early fifteenth century, it ensured its paper supply by establishing the Office for Papermaking.

—Hilde De Weerd

however, printing with movable type was practiced in Korea. In contrast to the first eleventh-century Chinese reference to earthenware movable type and the first extant Korean book printed in wooden movable type in 1377, thirteenth-century Korean titles were made with cast type. This suggests that these titles were the first in human history to be printed with metal movable type.

The first extant books printed with metal movable type date back to the early fifteenth century. In 1403 King Taejong (r. 1400–1418), the third king of the Yi dynasty (1392–1910), established the Type Casting Bureau, a government office charged with the production of bronze type. Within a few months the bureau cast a set

of about 200,000 characters. The king intended this type to be used for the printing of Confucian classics and scholarly texts. By then the court had adopted a civil service examination based on the model of the imperial Chinese civil service examinations. The king ordered the Office of Publications, which supervised the Type Casting Bureau, to print the classical, historical, and administrative texts necessary for the education of government officials. King Taejong's successors ordered at least eight other type sets between 1420 and 1777. The impact of the titles they produced was not limited to the literate Korean elite; Korean type also shaped Japanese cultural history. At the end of the sixteenth century, Japanese raiders took Korean type and typeset

books back to Japan. Their exploits heralded the beginning of the history of Japanese movable type printing.

European Printing

Printing with movable type—a single block for each letter and punctuation mark—was introduced to Europe in the early 1450s by goldsmith Johannes Gutenberg of Mainz. Although movable type printing is known earlier from China and Korea, the extent of East Asian influence, if any, on Gutenberg is unknown. Gutenberg's printing drew on existing technologies. Early printing presses resembled wine presses, and the new metal types, made from a compound of lead, tin, and antimony, were produced by the same process that produced coins and medals. Some technical innovations were associated with printing, however. Gutenberg devised an oil-based ink that bonded more effectively with the types than did traditional water-based inks. The best-known work of Gutenberg's press, the Gutenberg Bible, was finished by 1454 or 1455. Most were printed on paper, although a few special copies were made on animal-skin vellum. The edition, possibly of about 180 copies, sold out quickly, most of its purchasers being institutions.

It took several years for printing to expand from Mainz, at first in Germany and the German cultural sphere. A printer's shop appeared in Cologne in 1465 and in the small Benedictine monastery of Subiaco outside Rome the same year. Subiaco was dominated by German monks, and this initial venture was overseen by a German cardinal, Nicolas of Cusa. After 1465 print-

ing began to take off, carried mostly by German printers and entrepreneurs who spread the new technology throughout Europe. Printers were found in Nuremberg, Basel in Switzerland, and Paris by 1470, and William Caxton, the first English printer, set up shop in London in 1476 after learning the trade as a worker in continental print shops. Northern and central Italy, the highly urbanized heartlands of European humanism, were particularly dense with printers, and in the first 50 years of printing Italy would produce nearly half the European output of books. Printing reached Venice, which became one of its major centers for centuries, in 1469, and reached Milan the next year and Florence the year after that. Rome had a press by 1467, and the papal city of Avignon in southern France had a press by 1497. In the Italian south, printing was found in Naples by 1470 and Messina in Sicily by 1474. In the smaller kingdoms on the outskirts of Europe, printing reached Stockholm by 1473 and Lisbon and Copenhagen by 1489, but the first Scottish book was not published until 1508. (Before that date, Scottish writers used French printers.) In less urbanized eastern Europe, printing reached Cracow in 1473 and Buda in Hungary the same year, although the first evidence of printing in Prague is not until 1487. Businesses supplying the new printing industry's needs, such as paper mills, also expanded, as did booksellers.

Printing enabled for the first time in Europe the mass production of books and other written texts. About 8 million books, representing about 40,000 texts, were printed in the first 50 years of European movable type printing. This vastly increased the number of texts available to European readers. Most published texts were not original and included the Bible—a perennial seller—and established Latin and vernacular classics. A low-print run might be as few as 100 copies, but by the end of the century Italian printers were printing editions of over 2,000 copies. In format, early printed books mostly imitated the traditional European hand-copied manuscript book. The production of manuscript books did not cease with the spread of printing.

Printing required a substantial outlay of capital both to set up the printing shop itself with its specialized equipment and to pay the ongoing expenses of paper, ink, and labor, particularly the

literate skilled labor essential to some parts of the printing process. The market for printed texts was unpredictable, and several times overproduction of books led to a temporary crash in the local market. Many printing operations were short-lived, going out of business after producing one or two editions. To protect their businesses, printers sought local and regional monopolies as well as subsidies from monarchs, city governments, church authorities, universities, booksellers, wealthy individuals, and writers themselves. Although printing originally spread through production for the market and printers appealed to private investors for start-up capital, governments too seized the new technology. France had a royal printer by 1488.

The threat of the circulation of the printed word to authorities in state and church was apparent from early on. Papal bulls in 1487, 1501, and 1515 called for submitting manuscripts to the Church for prepublication approval (an *imprimatur*, Latin for “It may be printed”). Conservative religious establishments limited the spread of printing outside the western Christian world. Sultan Bayezid II of the Ottoman empire issued a decree against printing in 1485 at the behest of Muslim leaders fearing inaccurately printed Qurans. This decree applied only to Muslim printers, not to the Greek and Christian printers who were operating in Turkey several decades later as of 1515.

➤ EAST ASIAN MOVABLE TYPE PRINTING AND THE MOGAO CAVES

China devised printing well ahead of anywhere else, but most Chinese printing was done on wooden blocks, on which an entire page was carved, rather than with movable type. The large number of characters worked against movable type, as thousands of different types would be required. However, the Chinese did use movable type on some occasions. The inventor of movable type in China was, according to tradition, the eleventh-century Bi Sheng. Bi Sheng's type was ceramic and not very durable; later Chinese and Korean printers developed wooden and metal movable type. The Mogao caves of Dunhuang, a network of about 1,000 hand-carved grottos, on the Silk Road was a meeting point for centuries. Before it was extensively looted by early-twentieth-century European archaeologists, it contained thousands of Chinese and Sanskrit Buddhist manuscripts and some Christian scriptures in Syriac as well as secular and religious texts in Tangut, Tibetan, Uighur, and Mongolian. The Mogao caves also contained some of the world's oldest movable type, 48 pieces of late-thirteenth-century and fourteenth-century wooden type used in printing in the language of the Turkic-speaking Uighur people in China's northwest. The Uighur language was written with an alphabet, thus making it more suitable for movable type than character-based Chinese. Cave 17 also contained the earliest known printed book, a ninth-century *Diamond Sutra* printed in Chinese by the wood-block technique.

■ Introduction: Technologies of the Ocean and the Sea

Waterways have played a significant part in human history from earliest times. It was not only because the seas and rivers presented an abundance of food but also

because water offered the most efficient avenue for travel. Most roads were in poor condition, often not more than a trail. They often wound over hills and mountains and through deserts

and forests, making an overland journey full of hardships and dangers, especially when carrying a lot of supplies or merchandise. But above all, they usually took a long time to travel. In contrast, journeys up and down rivers or along-side shorelines were faster and safer as long as the ship or boat could avoid dangerous waters and bad weather. As trade developed, the demand for larger ships grew, and this in turn called for improvements regarding navigation and seaworthiness. This was much the case for the period 1000–1500 CE. There were seafarers all over the world who started to look beyond the known in search of new routes to distant countries. It was their ambitions, dreams, and curiosity that eventually came to have an enormous impact on future events.

Chinese shipwrights developed the junk in the second or third century CE, and during the Song dynasty (960–1279) it became the backbone of both the mercantile marine and the military marine. The size of the junk grew during the following centuries, and by the time of the early Ming dynasty (1368–1644) the Chinese navy was the largest in the world in both numbers and the size of its vessels. Chinese junks were equipped with stern-hung slung-rudders, which made them highly maneuverable. In addition, they used the compass to navigate and bamboo-slat sails with bamboo spars, which made them easy to handle. During the seven journeys of Zheng He (1405–1433), fleets, on some voyages of more than 300 ships and about 28,000 men, sailed along traditional trade routes in the Indian Ocean, traveling as far as eastern Africa. Although the size of the largest of these ships is highly debated and the evidence is scanty at best, it appears that some of the junks might have been anywhere from 300 to 400 feet (90 to 120 meters) long and equipped with more than three masts. However, these early Ming voyages came to an end due to their high cost as well as other factors, and after 1474 all the large ships were destroyed.

The ships used by Arabs, East Africans, Malays, and many others in the Indian Ocean were sewn in order to be able to disembark crew and cargo in shallow lagoons or on shores, as there were not too many good harbors available to them. The ships were equipped with lateen, or

triangular, sails, which made them exceedingly seaworthy, as they could sail both upwind and downwind—with and against monsoon winds—carrying bulk cargo all over the Indian Ocean.

In the Mediterranean, the merchant marines of the Italian city-states, primarily Pisa, Genoa, and Venice, had risen to prominence during the period of the early Latin Christian crusades of the late eleventh and twelfth centuries and seized control of the important trade routes between western Europe and the Levant. Light galleys were initially the primary warship, but by the end of the thirteenth century larger galleys for both war and trade were being constructed. Ship-building techniques changed, and ships were built upon frames with the use of better tools at large shipyards such as the Venetian Arsenal, which was established in 1320. Traditional round-ships, known as cogs, also became larger and could be equipped with up to three square masts erected upon multiple decks. These ships could sail to the northeast European markets in England and Flanders.

On the Iberian Peninsula, small open sailing ships known as caravels were developed. They were lateen-rigged, highly maneuverable, and used during the initial Portuguese expeditions along the West African shoreline in the early fifteenth century. As they could not convey sufficient supplies or men for longer voyages, however, the need for another vessel became imminent, as Portuguese mariners probed farther down the coast of Africa. The result was the *nau*, or carrack, a three- or four-masted combination of the north European cog and the caravel, which employed both square and lateen sails. This ship could carry men, supplies, and guns over the oceans, and its development greatly accelerated the European Age of Discovery during the late fifteenth century and beyond.

—Roine Wiklund

Technological Changes in Western Indian Ocean Shipping

The ships that carried the trade of the western Indian Ocean during the 500 years before the Portuguese arrived there were significantly different from the ships that were in regular use before 1000. They were typically bigger, faster,

safer, and better sailing vessels than those that had been used to pioneer the monsoon-based trade routes of the region. The ships of this era, while significantly improved compared to the vessels of earlier times, still shared some characteristics with them. These continuities made western Indian Ocean ships distinct from the vessels used in those parts of the ocean where Chinese ships predominated and from the vessels that were used in the Atlantic.

Oceangoing ships have been built in the western Indian Ocean since at least the fourth millennium BCE. Some of the earliest ships built in the region were made of bundles of reeds sealed with bitumen. Archaeologists recently found the remains of one such ship in Oman and are attempting to build a replica and sail it from Oman to India. By 900 CE, the standard features of the region's vessels had moved away from reeds to wooden planks that were joined to each other with wooden trenails (pegs). Craftsmen drilled rows of holes along the edges of the planks through which they passed cord to sew the planks together. The drill holes were then plugged with cotton soaked in shark oil. Once the planking had been finished, a frame was built inside the hull to stiffen it. It was lashed together rather than nailed. Thus, it was possible to build one of these ships entirely without the use of nails. Sewn ships have been used in other parts of the world—the Vikings built them as well—but nowhere have they been as widely used as in the western Indian Ocean. What is curious is that some of the people who seem to have favored these vessels did so despite having ready access to high-quality iron, so it is hard to believe that a shortage of iron explains the preference for sewn ships.

These ships were steered by means of a steering oar usually rigged to the right (starboard) side of the ship. Their sails were matting made of woven palm fronds rather than cloth, and the sails were simple square sails that hung from a horizontal yard. These vessels were capable of sailing the open sea in good conditions but probably were used more often in coast-hugging voyages that called frequently at local ports. Their steering oars were vulnerable to damage from heavy waves and did not give the steersman much control over his vessel, a critical point in rough seas.

➤ WHY SEWN SHIPS?

One of the things that historians of the western Indian Ocean have been wondering about for the last 50 years or so has been why sewn ships were so widely used in that region. The Italian traveler Marco Polo suggested that this was an adaptation to the presence of giant lodestones (magnetic rocks) on the seafloor that could draw the nails out of a ship that passed over them. This theory has not stood the test of time. It has since been suggested that iron may have been hard to come by in some places where people needed boats. This may have been the case in places such as the Maldives Islands, which are isolated coralline islands where boats were built entirely from coconut tree products. But in the continental ports of Asia and Africa, this explanation is less persuasive.

Another possibility is that sewn ships have some advantages in places where there are few good harbors. In much of the Indian Ocean, ships are taken into estuaries and lagoons to be loaded and unloaded. When the tide goes out they are left high and dry, with the hull resting directly on the bottom rather than being supported by the water. This places a great strain on the hull. In a nailed hull, the nails pull against the planking, eventually pulling through, and the planking has to be replaced. In a sewn boat it is the stitching that stretches and has to be replaced, but the planking is spared. In support of this theory, it has been noted that the last use to which sewn boats were put was the mangrove trade. Until the 1930s sewn ships were used to harvest mangrove wood, which required that boats sail into shallow channels at high tide where they were grounded as the tide went out. However, people now harvest mangrove wood using boats with nailed hulls and still allow them to be beached high and dry. So, no one knows for sure why Indian Ocean sailors were so fond of sewn ships.

—Erik Gilbert

The ships that emerged between 1000 and 1500 were significantly different. Perhaps most important, they used a new type of sail called a lateen sail. The name “lateen” is an anglicized form of the word “latina,” the word used by Iberian sailors to distinguish between the square sail and the triangular sail they associated with

the “Latin” ports of the Mediterranean. Lateen sails may have been in use as early as the sixth century CE in the Mediterranean Sea, but they did not filter into the Indian Ocean until roughly 1000. There they proved revolutionary.

The lateen sail uses a short mast that rakes slightly forward. To that mast is attached a long spar that sits at a roughly 45-degree angle to the hull. To the spar is attached a cloth sail that is almost triangular except that it has a small foot that hangs below the spar. The virtue of the lateen sail is that it can handle wind from just about any direction with ease. It sails downwind as well as a square sail but can also sail quite well into the wind. The only real drawback of the lateen sail is that the heavy spar it requires is difficult to handle.

The other new technology during this age was the stern post rudder. With a rudder hung off of hinges attached directly to the stern of the vessel, ships could dispense with their fragile steering oars, and helmsmen could use the larger size of the rudder and the greater leverage of the tiller to exert more control over their vessels.

These two technologies made the sewn boats of the Indian Ocean ships capable of open-water voyages over considerable distances. Direct voyages from India to Africa or from Arabia to India became commonplace. These more seaworthy ships played a central role in the growing commerce of the Indian Ocean, making it one of the most economically and culturally vibrant places in the world. They made the Indian Ocean the first ocean where bulky staples, in addition to the luxury goods that were a more normal feature of oceanic trade, were routinely transported over long sea routes.

Chinese Naval Technology

Early in Chinese history, most vessels were designed for use in rivers and canals. But as China developed, so too did its naval technology, with increasingly larger and more sophisticated ships including oceangoing craft. China witnessed a number of major developments in nautical technology in the years spanned by the Yuan (1279–1368) and Ming dynasties (1368–1644). Earlier, as China expanded its maritime trade during the Song era (960–1279), especially the time of Southern Song (1127–1279), the need for both a merchant fleet and a navy arose. Initially, this trade involved Japan, Korea, and the coastal areas of Southeast Asia, and seagoing ships were likely developed during this period. Indeed, the Southern Song empire was the first to establish an independent Chinese navy. This was primarily organized for coastal defense and went on to operate in the East China Sea. Later, the supremacy of the Song naval force was challenged by the Mongols, who had developed a fleet, largely comprised of Korean seamen and vessels, that enabled the hitherto steppe-based Mongols to wage war on the sea against both Song China and Japan. The culmination was the Mongol navy’s destruction of a Chinese fleet off the coast of present-day Hong Kong in 1279 and the drowning death of the last Song emperor, the seven-year-old Bing Di.

After the collapse of the Song dynasty, China’s new Mongol, or Yuan, rulers began an intensive program of ship construction at a series of different shipyards in China and in Korea. The new navy was engaged in unsuccessful naval warfare against Japan in 1274 and 1281 and Java in 1292–1293. Ships designed for coastal defense as well as maritime cargo produced in this period allowed Yuan China to dominate the East and South China seas.

In the following Ming period, the Chinese developed a main defensive fleet at Nanjing as well as a maritime transport fleet of several thousand ships. Chinese vessels now ventured into the Indian Ocean in greater numbers than ever before. Both naval combat and commercial ventures naturally inspired technological development. The Chinese created sea charts, discov-

ered new methods of navigation, and put together nautical treatises that included information on tides, currents, and cartography. The Chinese also experimented with paddle-driven craft; different kinds of rigging, including the use of cotton sails instead of bamboo matting; and ship armor. For naval warfare, the Chinese developed incendiary weapons, rockets, and ramming devices. Some of these innovations dated back to the Song era.

The vessel that served as the basic type for all Chinese navigation was the junk. Strength was an essential feature of Chinese ships, since the whole region of Southeast Asia suffers from violent storms known as typhoons (literally, “big wind” in Chinese). Chinese ships were some of the first in the world to feature a bulkhead, a partition inside the hull that makes the hull rigid even under extreme pressure. The bulkhead was related to the development of watertight compartments, a Chinese innovation from the Song period that prevented a ship from becoming completely flooded if part of the hull was damaged. Evidence suggests that the Chinese developed this idea from their familiarity with bamboo, which when split lengthwise reveals separate rectangular compartments called *septa*.

Archaeological evidence indicates that a fifteenth-century Chinese junk was much larger than European ships of the period. Chinese junks were flat-bottomed, allowing them to operate in shallow waters. A flat bottom, however, would normally render a vessel unstable in rough open seas.

Regardless of this inherent flaw, China’s advanced naval technology allowed the Chinese to carry out extensive missions of exploration and trade. Some of the most famous voyages were carried out by the Ming dynasty admiral Zheng He between 1405 and 1433; these voyages extended as far as East Africa. Zheng He’s fleet also carried out missions into Southeast Asia, India, and Arabia.

Western observers were quite interested in the sophistication of Chinese naval technology. Two late-medieval Venetian travelers, Marco Polo and Nicolo de Conti, spoke of various features of ship construction in China, such as the use of watertight compartments. The fourteenth-

➤ THE FIFTEENTH-CENTURY JUNK

The term “junk” is applied to a certain type of Chinese sailing vessel that had its origins in the Han dynasty (202 BCE–220 CE) and was further developed during the Song dynasty as overseas trade expanded. Different types of junks were constructed for inland waterways and for the open ocean. The word “junk” is from the Malay term *jong*.

One of the most distinguishing characteristics of the junk is the setup of the sails. The sails are rectangular but with elliptical edges and have bamboo inserts called battens. These provide the sails with stiffness and allow them to be quickly and easily furled and unfurled with relatively simple rigging. The sails of the junk have a shape much like an airfoil, and this allows the ship to sail relatively easily in a variety of wind conditions. Chinese sail configurations were different from those of Western ships of the period, with a staggered design that allowed agile steering as well as easier loading and unloading of cargo on the decks.

Junks also had a number of other distinctive features. Watertight compartments, which could be reached by way of separate hatches, prevented a ship from sinking even if part of the hull had been breached. The sternpost rudder was developed very early in China; this is a flat board that can be lowered on a post at the stern of a ship when the vessel enters deep waters and allows for precise steering. Traditionally, junks were constructed without a keel, allowing them to operate in shallow waters. Therefore, the sternpost rudder served as both a rudder and a keel in the open ocean. Junks also had multiple masts, allowing a great number of sails and thus greater speed. The Ming dynasty saw the construction of some of the largest junks, some 400 feet (122 meters) in length, with a range of types being assembled for the voyages of the famed admiral Zheng He.

—Benjamin B. Olshin

century Islamic traveler and writer Ibn Battuta commented on the complex sail configurations used on Chinese ships as well as the sheer size of the vessels. In the twelfth century, the Chinese also possessed certain sophisticated navigational techniques, including the ability to determine

position through observation of the stars and the use of the magnetic compass. Early Chinese maps reveal an advanced knowledge of the Indian Ocean and even the peninsular shape of Africa well before European explorers had rounded the Cape of Good Hope.

Despite the power and sophistication of the Chinese fleet in the Ming era, the Chinese did not carry out many extensive overseas voyages after those of Zheng He. The fifteenth century would see the beginnings of European sea power, as English, Dutch, Portuguese, and Spanish fleets began to venture to Africa, Asia, and the Americas.

Innovations in Mediterranean Shipping

Mediterranean shipping went through considerable changes during the period 1000–1500 that ultimately led to the development of the full-rigged ship that made European transoceanic exploration possible. The Christian crusades, beginning in the eleventh century, and the Latin Europeans' recapturing of Mediterranean islands depended upon powerful navies for support; as Muslim naval strength in the Mediterranean weakened, that of the northern Italian city-states grew powerful.

Even though information about ships for the period 1000–1250 is scarce, there are some archaeological findings, written sources, and illustrations that cast a bit of light on the issue. It appears that Muslim and Byzantine shipping did not differ to any great extent, even though they used a variety of ship types, all carvel-built (hull planks lying edge to edge rather than overlapping, as with clinker-built vessels). The Byzantine merchant ship was usually quite small and was driven by a single lateen sail. It had a characteristic round appearance due to its curved stem posts and sternposts (the principal vertical timbers at the bow and stern) and became the model for most sailing ships until the end of the thirteenth century. The Muslims probably introduced a few ship types from the Red Sea and the Indian Ocean. The *tarida* may at first have been a reed canoe, but *tarida* later became the name of a small Genoese coastal trader equipped with oars and a large lateen sail. Another ship commonly used was the *carabi*, or *qarib*, a small and often undecked ship probably built after Byzantine design.

Galleys were the primary warship of the Mediterranean since antiquity, even though they could be used for transport and trade as well. The light galley, *galee sottili*, became the main warship in the navies of the Christian West, especially those of the Italian maritime cities. These narrow galleys cut through the water in pursuit of their enemies. They were about 130 feet (40 meters) long and were equipped with more than 50 oars on each side. The oars were pivoted from tholepins on an outrigger, which made the deck extend over the hull of the ship. Galleys

were often equipped with a curved beak, the *calcar*, instead of the traditional ram, or *rostrum*, favored in antiquity. The beak was fixed at the bow but was above the water line, so it could be used as a bridge when boarding enemy ships or to immobilize them by shattering oars and the upper hull. The galley had one mast with a lateen sail that was used whenever possible to rest the oarsmen, who otherwise operated one oar each.

Generally, galleys did not cross open sea but instead hugged the coastline. There are numerous examples of whole fleets going under in bad weather. Another reason to stay near land was the low stowage capacity of galleys. The large crew required huge quantities of fresh water and food, which could not be stored onboard the narrow ship. Oarsmen were often paid volunteers (or sometimes drafted free citizens) on Western galleys, while Byzantium and the Muslim states normally used conscripts. When the cost of employing oarsmen increased at the end of the fourteenth century—for instance, due to population decrease after the bubonic plague—it became more usual that convicts and prisoners of war manned the oars. No significant improvements were made on the war galley until the end of the thirteenth century, when a second mast was added together with a third oarsman per bench; earlier one or two oarsmen were used.

Italian shipyards, like the arsenal in Venice, derived from the Arabic *dar al-sina* (dockyard), went through substantial changes from the end of the eleventh century. New shipbuilding techniques were introduced, and a number of tools and other technical aids were developed. The skeleton system was introduced from Byzantium, meaning that ships were built upon frames and that the hull planking was added later. Construction of the keel needed highly skilled carpenters, whereas the planking and maintenance could be done by workers with less expertise, which led to a division of labor. During the thirteenth century planks were produced in frame-saws, which decreased the amount of spoiled wood compared with the earlier way of splitting logs. Tools like the auger, ax, and handsaw improved as well and enabled carpenters to construct ships faster and cheaper.

THE ISLAND TRADE ROUTES OF THE MEDITERRANEAN

Portolan chart of the Balkan coast, undated.
(Jupiterimages)

Trade between Europe, Africa, and coastal Southwest Asia was vital to the economies of these regions, but shipping was limited between late March and early November in order to avoid winter storms. The trade routes at sea followed the northern coastline, if possible, for a number of reasons. The chain of islands there provided shelter in bad weather and protection from corsairs. The islands also offered trade opportunities and the possibility to replenish supplies and fresh water. In addition, deep water, together with good visible landmarks, made navigation near land easier and safer. Even the currents and the wind made the northern routes more favorable. The North African coastline, on the other hand, was treacherous, with its rocky cliffs and reefs stretching out to sea. Because of their strategic importance, the islands of the Mediterranean, from the Balearic Islands in the far west to the islands off the coasts of Greece and Southwest Asia in the Far East, were constant objects of conflict and conquest.

—Roine Wiklund

Italian ships became larger, and new types developed during the thirteenth century in response to the Italians' intensified activities in the eastern Mediterranean, especially in regard to the crusader states. One innovation was the great galley, a merchant galley with three masts,

usually lateen-rigged but sometimes set with a square sail on the mainmast. The great galley was designed to proceed under sail, while oars were mainly used to enter and exit harbors. The new design with a high bow and hull made it more seaworthy than its predecessors, and it could sail the high seas and travel over the Atlantic to the important marketplaces in England and Flanders. Even the traditional round-ships evolved and were built with two or three masts erected upon two, often three, decks. Castles were erected at either end to accommodate passengers. However, sailing ships were still difficult to handle and had rather poor upwind capabilities.

Navigation improved throughout the period. During the eleventh century it was common to sail close to the coast and use landmarks for guidance. Another means was to study the position of the sun during the day and the stars at night, either with bare eyes or with the help of an astrolabe (Arabic *asthar-lab*, “to take a star”). Portolan charts—detailed coastal charts with marked directions for winds and currents—appeared in the thirteenth century. With the introduction of the compass during the twelfth century, from possibly China by way of the Islamic world (but there is no clear evidence of transmission), mariners knew the direction even if they were at sea on a cloudy night. Other aids were the hourglass and the knotted rope, which were used to measure the speed of the ship. A log tied to a rope with knots at regular intervals was thrown overboard, and as the log drifted astern the knots could be counted and timed by an hourglass.

The Northern European cog was known in the Mediterranean since the thirteenth century. It was totally different from the round-ship and had a single mast rigged with a square sail, straight stem posts and sternposts, and a single sternpost rudder, probably a Chinese invention adopted by the Muslims before it spread to Europe. While the cog had some advantages, it could not sail into the wind as well as lateen-rigged ships.

The caravel, probably originated from Arab fishing boats, developed in Portugal from the mid-thirteenth century. Caravels were up to 100 feet (30 meters) long and equipped with two

masts rigged with lateen sails. The ship was highly maneuverable and was used by Prince Henry the Navigator during the exploration of the African coastline during the fifteenth century. However, the ship could not carry enough supplies for longer voyages.

The two ship types northern cog and southern caravel merged, probably by Iberian shipbuilders, during the fourteenth century. On Pizigani's portolan chart from 1367 a new ship type was depicted with a square sail at the main mast and a lateen sail at the mizzen mast. It also had a curved stem post and a straight sternpost, where the rudder was mounted. This ship, the carrack (in Spanish *nao* and in Portuguese *nau*, meaning “ship”), was a large cargo ship but also had military abilities. High castles fore and aft provided good defense, while cannons presented a lethal threat to all adversaries. A third mast rigged with another square sail was introduced during the fifteenth century, making the carrack a full-rigger. Combined fleets of carracks and caravels carried European explorers like Columbus to America in 1492 and Vasco da Gama to India in 1498, beginning the European Age of Discovery.

Innovations in Atlantic Ships—Caravels, Naus, and Carracks in the Age of Discovery

The need to design and build seaworthy ships was one of the greatest challenges confronting the Europeans in the quest for overseas expansion.

To complicate matters, European ships around 1400 were generally inferior in design and construction to vessels in most parts of Asia. During the next hundred years a minor revolution took place in shipbuilding theory and technique, especially in southwestern Europe. These developments yielded new types of hybrid sailing vessels called the caravel, the *nau*, the carrack, and finally the galleon. The necessities of exploration and expanding empires largely determined these changes. The caravel was the ideal vessel for exploration and discovery and was used by both Vasco da Gama and Christopher Columbus. The square-rigged naus and even larger full-rigged carracks became the preferred vessels for transporting the goods of Asia and the Americas during the initial decades of the sixteenth century. The more powerful galleon served to protect such fleets and would come to symbolize the imperial power of Portugal and Spain by 1550.

The caravel, nau, and carrack all combined elements of Atlantic and Mediterranean ships as well as elements of Arab vessels sailing in the Indian Ocean. These ships possessed three masts (Mediterranean), a square main sail (Atlantic), and a lateen (Arabic) or triangular mizzen, or rear, sail. Of the three, the Portuguese initially concentrated on the caravel. The flush planked hulls of these ships, built skeleton first, made them very durable, while a length to breadth ratio of about 5:1 made them very seaworthy. Caravels were not particularly large, perhaps 65–80 feet (19–25 meters) in length and with a shallow draft that displaced between 80 and 130 tons of water. Caravels were far from comfortable. They were generally open to the elements, with perhaps one small cabin aft, and they could not carry many men, supplies, or weapons. Yet these vessels were ideally suited to the main work that was required in the Age of Discovery: exploring unknown coastlines and handling close to the wind. From about 1420 onward, caravels were used to great effect by the Portuguese exploring the Atlantic islands. Nevertheless, the caravel was not well suited for the demands of maintaining and protecting an empire. As naus and the larger carracks began to carry increasing numbers of guns, especially below deck, the caravel found itself increasingly supplanted by these more powerful, if initially less seaworthy, ships.

➤ THE PINTLE-AND-GUDGEON RUDDER

The pintle-and-gudgeon (PG) rudder is composed of a rudder fastened on the sternpost with iron bolts vertically inserted in the rudder and attached to rings in the stern, like three or more pairs of hinges. This system was developed in northern Europe, most likely during the eleventh century. As trade increased, the development of larger ships demanded a new steering system with better performance, which made the traditional use of fixed quarter rudders obsolete.

Sternpost-mounted quarter rudders had been known and used in Europe since the Late Roman period on barges traveling the Rhine, but the technique probably originates from ancient Egypt. The slung rudder used in China from the first century CE is another independent invention with a different suspension and steering mechanism compared to both the European and Arab systems.

The earliest depictions of PG rudders in Europe are from Norman baptismal fonts made in the second half of the twelfth century and on town seals from the thirteenth century. Ships equipped with quarter rudders were by 1252 distinguished from those having a stern-mounted PG rudder according to the Port Books of Damme in Flanders.

—Roine Wiklund

Between 1450 and 1500, caravels and the larger naus coexisted on voyages of discovery. Columbus's fleet consisted of a nau, the *Santa Maria*, and two caravels, the *Niña* and *Pinta*, while many Portuguese fleets, including that of Vasco da Gama, consisted of both naus and caravels. On these voyages the caravels carried dispatches between ships and explored rivers and coastlines, while the naus hauled most of the fleet's manpower, firepower, and supplies. By the early 1500s, however, these voyages of discovery were giving way to the needs of the growing empires of the Europeans in Asia and the Americas. For ships this meant the need for more cargo space and artillery mounted below deck, which in turn mandated larger and broader ships. Despite the fact that artillery pieces had been mounted on caravels by the Portuguese since

the 1450s, there were serious problems with adapting the caravel to large-scale naval combat. Above all, their relatively small size placed definite limits on the effective firepower of such vessels. As the need for larger, heavier, and more powerful shipborne cannon became more acute, first the full-rigged naus and then the carracks had clear advantages. Naus could carry more cargo than the caravel, and for the Portuguese and Spaniards, the larger the cargoes the better. In the early sixteenth century naus became more seaworthy, and this development spelled the death knell for the caravel. At the same time, the allure of rich Iberian cargoes to pirates and European rivals created the need to combine cargo-carrying and military capabilities. The carrack developed to fulfill this task. Possessing huge storage capacity, these ships were designed to overawe any and all attackers by presenting a

formidable defensive front. Carracks were built with extremely high castles fore and, to a lesser degree, aft. These ships also were probably the first sailing ships to mount heavy guns low in the hull behind watertight gun ports, and weapons were also manned from the crow's nests at the tops of the masts. The carrack projected a menacing appearance to all approaching ships.

ERA 6 The First Global Age, 1450–1770

Introduction: Intensified Hemispheric Interactions

In March 1769 a merchant in a Boston coffeehouse in the British North American colony of Massachusetts could pick up a copy of *American Magazine* to read about the activities of French missionaries across the world in China. Sipping his Bohea tea plucked from the Blue Mountains above Canton, sniffing the aroma of coffee and chocolate carried from the Arabian port of Mocha, perhaps sprinkling cinnamon from India or nutmeg from the Spice Islands of the “great South Sea” over his beverage, he could ponder the “genius and customs of the inhabitants of China” described in the essay. He might consider how he was increasingly integrated into a global economy and a global culture, reflect on how this has emerged since Columbus’s accidental achievement, and wonder what connections the future would bring to the world.

How extensive were these encounters? *American Magazine*, read by our Boston reader in 1769, argued that the Chinese “have no opportunity of being acquainted with the different nations of Europe.” Although the report expressed a rough European admiration of China around 1800, the novelty of China diminished in Europe as a consequence of increased contact in Asia. As the subtitle for the volumes for this era suggests, the main theme of world history during this period was unprecedented patterns of contact and encounter among Asia, Africa, Europe, and the Americas. These contacts surely set the foundation for the imperialism of later eras, but historians debate the extent of the contacts as well as their effects on societal changes worldwide.

In 1450 the world was a very different place from today. There were no modern nation-states, and Europe did not hold any worldwide economic or political power, which was largely in the hands of Asian states, especially China and India. Asian political and economic activity was delineated by the four great trade corridors of the time, incorporating many specific routes that linked an Afro-Eurasian economy with the Mediterranean, central and east Asia, and south and southeast Asia. A northern caravan route led from the Black Sea through central Asian lands to China, although this route had diminished by about 1350. A central route connected the Mediterranean Sea and the Indian Ocean, with caravans crossing Baghdad and the Middle Eastern deserts and ships carrying trade across the Persian Gulf and the Indian Ocean. Southern caravans followed a route from Mamluk Cairo through the Red Sea to the Indian Ocean and points east, while the great trans-Saharan route connected North Africa with the savanna states of the south. Yet by the end of the era in 1770, vessels crisscrossed the world’s oceans regularly,

linking Asia, Africa, Europe, Oceania, and the Americas. The establishment and intensification of interregional trade connections among these world regions was one of the most important developments of this era. Equally important, in this period a modern political and social consciousness emerged that redefined the world politically, intellectually, and socially.

Socially, most human societies were divided into social classes and hierarchies characterized by unequal access to power, privilege, and other resources. These divisions often took the form of elaborate ideological systems based on shared religious beliefs. The medieval concept of dividing human society into three orders of those who pray, fight, and work (clergy, nobility, and the rest, respectively) experienced a major transformation. Although formation of social groups and classes bore peculiar marks of indigenous customs and traditions, some general observations can still be made. Whether in Africa, Asia, the Americas, or Europe, at the top of most social pyramids were emperors, kings, and sovereigns of various kinds. Their families, augmented by a large aristocracy, comprised a social group by themselves, and their internal struggles were frequently the source of much political (and social) conflict. Beneath them we can identify several groups that were common to most societies: religious officials and authorities, state officials and administrators, soldiers and servants, merchants and artisans, free peasants, and slaves and serfs. Naturally these were not rigid categories, and some often overlapped or blended together or were missing completely. Thus, in Europe successful merchants often bought titles and meshed with the aristocracy; in the Ottoman empire and Mughal India, state officials could also be religious leaders; in Ming China, landowning aristocrats were largely absent.

Most historians agree that the period between 1450 and 1500 marked a turning point in world history. The once-mighty Abbasid caliphate had passed away, as did the Mongol empire with its famous Pax Mongolica (Mongol Peace) that facilitated commerce and communication between East and West for about a century between roughly 1260 and 1360. They were replaced by a host of new powers, the most important being the Ottoman Turks, who conquered Anatolia (present-day Asiatic Turkey), established a large foothold in southeastern Europe, and finally destroyed the last vestiges of the Byzantine empire in 1453. Just 50 years later another major Muslim power rose in Iran, where the Safavid dynasty was established, and in 1526 the Mughals, descendants of Chinggis Khan and Tamerlane (Timur) out of present-day Afghanistan, seized power in northern India. In China, the Ming dynasty (1368–1644), which came to power following the expulsion of the Mongols, raised the Chinese state, commerce, and culture to new levels, probably best reflected in a series of major expeditions launched to various corners of Asia and East Africa starting in 1405. These expeditions were ended by imperial decree in 1433. Although this decision did not isolate China from the outside world, it nevertheless put an end to Chinese efforts to actively conduct maritime exploration and instead concentrated on eastern central Asia. Yet historians, mainly Western scholars trained at Western universities, traditionally have written the story of this era

as the “rise of the West.” Enamored of Western progress in technology and organization, scholars have often shaped the story to highlight European advancement and expansion. These assumptions about a narrative of European power stem from our location as well as our need to understand our history. However, utilizing a narrative of European dominance has influenced our criteria for choosing what is relevant to this history. It has helped us form a master narrative, a grand schema for organizing the interpretation and writing of history. Therefore, in order to better understand the entire world in the early modern era, we need to consider alternative narratives to historical development during this time, narratives that draw from regions outside of Europe.

Therefore, in order to better understand the entire world in the early modern era, we need to consider alternative narratives to historical development during this time, narratives that draw from regions outside of Europe.

Indeed, recent research has challenged the conventional story, and a new generation of historians has developed more sophisticated narratives. They have moved beyond the nation-state as the central actor in these narratives to embrace oceans. In addition, historical research illustrates how the assumption of a European exceptionalism during this time is inadequate and incorrect and that there were concurrent economic and political developments in Asia and Europe some 500 years ago.

Population and Land

Evaluating world population changes offers important insights into the early modern era. The world population doubled during the three centuries covered in this volume. But determining a precise number of people living in the world presents a difficult problem. Even today, despite modern census techniques and technological advances, estimates of the world population still have some margin of error, so one can only imagine the challenge of ascertaining population in the early modern era. Most scholars agree that around 1400 the world population was between 350 million and 400 million, and by 1800 it doubled to about 700 million to 750 million. China and Europe each contained about a quarter of the world population.

Human population changes were not uniform around the world. Looking at western Europe, three broad periods of population expansion can be established. Its population rose significantly between 1100 and 1300. The arrival of the bubonic plague in 1347–1348 reduced Europe’s population by 45 to 50 percent within a few years, but the population grew again by 1450 and continued its rapid increase until around 1650. However, other regions of the world experienced completely different demographic dynamics in this period. The population of the Americas was probably around 100 million by the late fifteenth century, but it experienced a catastrophic decline following Christopher Columbus’s voyage to America in 1492. The native population of central Mexico is estimated to have declined from over 25 million in the early sixteenth

century to about 1 million a century later. Similarly, sub-Saharan western Africa suffered a long drain on its population as a result of the European slave trade that began in earnest in the sixteenth century. These slaves were brought to both North and South America. Thus, by the end of the eighteenth century, Brazil had about 2 million blacks in a population of 3.25 million people, while the newly established United States of America's census of 1790 showed that blacks represented almost 20 percent of its population of 3.9 million people. Nevertheless, the introduction of new crops from the Americas helped offset Africa's population loss, and sub-Saharan Africa also experienced a population upsurge.

Between the fifteenth and eighteenth centuries the vast majority of humans worked in agriculture, with 80 to 90 percent of people living from the land. Therefore, human lives were subject to the rhythm and quality of harvests, which in turn depended on climatic changes. As a result, human population was influenced by climatic rhythms. In the fourteenth century there was a global cooling in the Northern Hemisphere, with winters becoming colder and more severe. As a result, the Viking colonization of Greenland ended. Another Little Ice Age, as this cooling down became known, occurred between the late seventeenth and early eighteenth centuries. In Europe this cooling meant that snow and ice remained in fields until late in the year, and grains and vegetables no longer had time to ripen. In the 1690s western Europe experienced the coldest decades in 700 years, which resulted in widespread famine, misery, and unrest as peasant uprisings shook some of France's provinces.

The Islamic World

Three significant Muslim empires emerged in the fifteenth and sixteenth centuries: the Ottomans centered in the heart of the former Byzantine empire, the Safavids in Persia (Iran), and the Mughals in India. These three so-called gunpowder empires employed advanced military technology and organization to rule lands that extended from Europe and North Africa to Southeast Asia. As a result, the empires combined to dominate most of Afro-Eurasian trade at that time. Thus, Europeans admired and feared the power of Muslim empires. After the fall of Constantinople (present-day Istanbul) in 1453 (and the reformulation of the city as the capital of the Ottoman empire), the Ottomans spread their reach to the gates of Vienna less than a century later. By 1600 the Safavid empire became a formidable opponent of the Ottomans, controlling a vast territory from Afghanistan to Iraq. Farther east, the Mughals controlled most of the Indian subcontinent and parts of Afghanistan, while small Islamic khanates controlled much of western and eastern central Asia.

In this major portion of Dar al-Islam (the Abode of Islam, namely lands under Muslim rule), we see many political, social, and intellectual developments. In addition to acquiring vast territories of the known world, these Muslim empires supported impressive artistic and cultural achievements, represented in literature, art, and architecture. For example, the Ottomans adopted and strengthened the rich historical tradition that had flourished since the early Muslim empires. In the fifteenth

century they commissioned historians to write official chronicles and, by the end of the seventeenth century, established an Imperial Historiographer. The distinctive Ottoman architectural style incorporated the Byzantine architectural tradition, as seen in such masterpieces as Sinan's Suleiman Mosque in Constantinople (Istanbul). In India, Mughal art and architecture blended Iranian and Indian styles, as most famously expressed in the Taj Mahal. And when we study the Ottomans and Mughals we learn about a remarkable level of tolerance, as non-Muslims were central to the economic success of these empires.

The expansion of Indian Ocean trade linked the Ottomans, Safavids, and Mughals to China and Southeast Asia. The fifteenth through seventeenth centuries were a particularly dynamic period of contact and encounter in Southeast Asia, the "land below the winds," as commercial engagement established the early contours of a global economy. South and Southeast Asia produced the cloves, nutmeg, pepper, and other spices that drove long-distance trade, essential to the commercial boom of the time, and the cities and seaports of the region were centers of economic and cultural vitality. Trafficking in the region's spices seems to have surged suddenly around 1400 and continued to expand with growing demand in Europe and China. This trade brought enormous wealth to India and China and also facilitated the spread of religion. Following earlier trade routes, Muslim traders brought goods as well as religion to Southeast Asian centers such as Malacca.

South and Southeast Asia produced the cloves, nutmeg, pepper, and other spices that drove long-distance trade, essential to the commercial boom of the time, and the cities and seaports of the region were centers of economic and cultural vitality.

The Ottomans

By the late sixteenth century the Ottoman empire was one of the most powerful empires in the world. It began as a small principality in western Anatolia (Turkey) that pursued aggressive expansionist policies in the fourteenth century. Claiming the title of *ghazi* (holy warrior), the Ottoman leaders turned the concept of the jihad (holy war) into one of the major components of their foreign policy and gradually absorbed neighboring peoples and states in Anatolia and the Balkans. Under the reign of Sultan Mehmed II (r. 1451–1481) the Ottomans rapidly expanded. With almost all of Anatolia under his control, Mehmed II besieged Constantinople, the capital of the once-mighty Byzantine empire, and captured it in May 1453. The six-week siege of Constantinople is one of the most dramatic and consequential events in world history. It marked the end of a 1,000-year-old eastern Roman, or Byzantine, empire and the beginning of the imperial phase of the Ottoman state. The loss of Constantinople also exposed eastern Europe to a new wave of Ottoman expansion.

Sultan Selim I (r. 1512–1520) led triumphant campaigns in the east, defeating the Iranians in 1514 and capturing Syria and Palestine in 1516

and Egypt in 1517. By the end of his rule the Ottoman state extended from Iraq to Serbia and from Anatolia to Tunisia. His son Suleiman (r. 1520–1566) only further enhanced Ottoman power as he led his armies on 13 major campaigns and numerous minor ones. In 1526 he crushed a Hungarian army at Mohacs; three years later he besieged (unsuccessfully) the Austrian capital of Vienna and secured Ottoman dominance in the eastern Mediterranean. Beside military achievements, Suleiman's reign saw major legal and administrative reforms, which earned him the Turkish title “Kanuni” (the Law-giver) throughout the empire. His reign also witnessed extraordinary literary, artistic, and architectural flowering. Thus, Piri Reis, the geographer and cartographer, produced maps of the world that had a level of accuracy unparalleled for their time. Sinan, a contemporary of Michelangelo whose architectural skills he rivaled, produced over 300 masterpieces—mosques, schools, hospitals, etc., that revitalized Islamic architecture. The grandeur of the Ottoman state so impressed Europeans that they called Suleiman “the Magnificent.”

Suleiman's reign proved to be the Golden Age for the Ottoman empire, as new challenges arose over the subsequent two centuries. The Ottoman empire saw a series of less able rulers who failed to maintain their predecessors' policies. The Janissaries, elite troops of male Christian children levied through the *devşirme* system (a tax also known as the child-collection tax, in which Christian boys from the Balkans and Anatolia were taken from their homes, enslaved, and converted to Islam), came to wield such prestige and influence that they dominated the government and blocked any reforms that threatened their status. More importantly, the European Age of Discovery had a profound effect on the Ottomans. As European merchants discovered direct sea routes to Asia, international trade, which previously passed over the Ottoman empire, shifted to oceanic routes. The Ottoman state lost vast revenues as a result. Ottoman guilds and craft industries failed to modernize and often resisted change, which led to their falling behind European competitors. Increasingly, Europeans turned to the Ottoman empire as a source for raw material, which Europeans used to manufacture goods and sell them back to the Ottomans, undermining Ottoman industries. The Ottoman government only facilitated this process by approving special commercial agreements, known as capitulations, with Europeans. Starting in the mid-sixteenth century, a series of capitulations exempted European merchants from Ottoman laws and taxes and eventually ensured their dominance over Ottoman trade and manufacturing.

In the seventeenth and eighteenth centuries the Ottomans did show occasional glimpses of past grandeur while responding to political and economic challenges. During the tenure of the capable grand viziers from the Koprulu family, major domestic reforms and vigorous foreign policies were attempted, but they ultimately failed to produce decisive results. The second Ottoman siege of Vienna in 1683 was the last time that the Ottomans seriously threatened central Europe. The subsequent Treaty of Karlowitz (1699) marked a turning point in Ottoman history, as Sultan Mustafa II (r. 1695–1703) was forced to surrender Hungary and Transylvania to Austria. This event is often considered to

be the beginning of the long decline of the Ottoman empire. In the eighteenth century the Ottomans were engaged in prolonged conflicts against European states—most importantly against the rising Russian empire which fought the Ottomans five times within that century—that exhausted Ottoman treasuries and contributed to internal turmoil.

Safavid Persia

In the early sixteenth century the Ottoman empire saw the rise of a powerful competitor in Persia (Iran). After a prolonged dominance by Arabs and Mongols, Iran emerged as a powerful state under the leadership of the Safavid dynasty. Founded by Ismail (r. 1501–1524), the Safavids embraced Shia Islam (as opposed to the Sunni Ottomans) and gradually united all of Iran under their rule. Yet this process was wrought with challenges. In 1514 Sultan

Selim I routed Ismail's army at Chaldiran, and in the mid-sixteenth century repeated Ottoman attacks kept Safavid power in check. The Safavids drastically changed with the accession of Shah Abbas to the throne in 1587. A brilliant statesman and commander, Shah Abbas presided over a rapid territorial expansion and a cultural and economic blossoming. To consolidate his rule, he began a systematic inclusion

of Georgians and Armenians in his newly established standing army of slave-soldiers known as ghulams, which he used to suppress domestic revolts and coerce disloyal provinces into submission. In 1598 he established contacts with England after an English trade delegation arrived seeking a commercial partnership. With these contacts Abbas greatly expanded and modernized his army, which he then used to expand his sphere of influence to Georgia, Armenia, Afghanistan, Kurdistan, and Azerbaijan. Iranian forces also crossed the Straits of Hormuz and occupied Oman. In 1623 as the Ottoman empire suffered internal turmoil, Abbas invaded Iraq and Anatolia, capturing Diyarbakir, Baghdad, and Mosul. By then the Safavid state was at its greatest territorial extent.

Shah Abbas facilitated the development of Iranian craft industries and trade. During his campaigns in the Caucasus he resettled tens of thousands of Georgians and Armenians in Iran, where they helped to develop agriculture, trade, and various industries. He transferred the capital from Qazvin to Isfahan, turning it into a thriving center of arts, craft-based industry, and commerce. Visiting this city, the European traveler John Fryer was dazzled by Isfahan's markets, noting that the city was "the surprisingest piece of Greatness in Honour of Commerce the whole World can boast of, our Burses [markets] being but Snaps of Buildings to these famous Buzzars."

Shah Abbas's death in 1629, however, was a watershed moment in Iran's history. Similar to the Ottomans, Abbas ended the practice of sending royal princes to govern provinces, and consequently most shahs

The Safavids drastically changed with the accession of Shah Abbas to the throne in 1587. A brilliant statesman and commander, Shah Abbas presided over a rapid territorial expansion and a cultural and economic blossoming.

after him lacked the necessary skills and experience. By the 1720s the country was torn by vicious civil strife, as various pretenders fought for the Crown. Nadir Khan of the Afshar tribe emerged the victor in this conflict, and in 1736 he proclaimed himself shah. Nadir was a brilliant military commander whose campaigns revived an Iranian empire. Despite his successes, Nadir came to be regarded as a cruel and capricious tyrant and faced a number of internal revolts and conspiracies, one of which resulted in his assassination in 1747. His death plunged Iran into a civil war once more that continued for three years and led to the rise of the Zand dynasty. Although its founder Karim Khan proved himself a capable commander who reclaimed all of Iran by 1760, his success was fleeting, and political disorder and economic decline again characterized Iranian life. His death in 1779 led to another round of violence that further weakened the Iranian state.

Mughal India

By 1450, there had been a long presence of Muslim communities in South Asia. One of the most influential Muslim kingdoms in the region was the Delhi Sultanate, an empire that ruled large parts of northern India from approximately 1206 until 1526. In 1526 a ruler from Kabul named Babur defeated the last sultan of Delhi and established what would become one of the most prominent, wealthy, and powerful empires in the early modern world, the Mughal empire. Babur only ruled the empire for a few years, but his descendants helped to build an empire that at its height ruled almost the entire Indian subcontinent with impressive political and cultural achievements.

The Mughals developed an empire with an advanced military, new administrative structures, and extensive cultural and artistic developments. Many of these achievements began during the rule of Akbar, who ascended to the throne as a teenager in 1556. He ruled until 1605 and became a defining leader of the empire. Akbar expanded the territory of the empire to include large parts of northern India. His father, Humayun, developed an interest in Persian art, literature, and culture when he was forced to flee to Persia (Iran) during part of his reign. This double connection between Persian and Indian cultures and Islam and Hinduism helped to define the empire, and Akbar and his descendants continued to support new systems of art, culture, and architecture. The Mughals encouraged an artistic and aesthetic courtly culture, patronizing music, court poets, and a new genre of painting. Architecture became an important legacy of the Mughals as well. The emperor Shah Jahan (r. 1628–1658) presided over many architectural accomplishments, including patronizing the building of the capital at Delhi and the famous Taj Mahal.

The Mughals ruled a territory that included a diverse group of people, and most were Hindu. As a result they developed a sophisticated approach to religious issues. The Mughals were realistic Muslim leaders who treated Hindus as *dhimmis* (protected groups). In addition, a substantial number of Hindus served in the Mughal administration,

including the imperial cabinet or as royal advisers. Under Akbar, special taxes on non-Muslims were repealed. In addition, Mughal rulers sought interfaith marriages in order to develop ties to different communities. Akbar's interest in interfaith dialogue became the basis for his *ibadat khana* ("house of worship"), a place where representatives of various religions, including Jesuit missionaries from Europe, were invited to engage in debates and discussion. As a result of these developments the Mughal empire encouraged a fusion of cultures, religions, and ideas. Even under Aurangzeb (1568–1707), a leader known for a more conservative approach to Islam, Hindus were still vital to the administration.

The Mughal empire eventually included most of South Asia under the rule of Aurangzeb by the late 1600s. Their political, military, and cultural success drew the interest of people worldwide, and European travelers were amazed at the wealth and power of the Mughals. After Aurangzeb's death, Mughal rulers increasingly relied upon regional leaders to maintain the empire. By the middle of the eighteenth century the British East India Company, a corporation that formed to take part in the spice trade, became the administrator in several areas under Mughal authority. Yet the empire lasted until 1858 and served as a model for various empires in the early modern era.

Akbar's interest in interfaith dialogue became the basis for his ibadat khana ("house of worship"), a place where representatives of various religions, including Jesuit missionaries from Europe, were invited to engage in debates and discussion.

East Asia

China

One of the defining moments in Chinese history took place in the thirteenth century when the Mongols penetrated China's defenses and conquered its vast territories, establishing the Yuan dynasty that ruled China until 1368. Mongol repression, economic difficulties, and social changes eventually combined to cause the Red Turban Rebellion, which overthrew Mongol rule and established the Ming dynasty (1368–1644). Begun by the Red Turban leader Zhu Yuanzhang, who became Emperor Hongwu (r. 1368–1398), the new dynasty remained in power for over 250 years and initially achieved a remarkable revival of the country. Before the Ming dynasty years of turmoil led to economic chaos in some regions of China, where irrigation systems were damaged, vast farmlands were abandoned, and commerce was interrupted. The Ming dynasty succeeded in reviving agriculture, in large part by pushing through improvements in rice cultivation. The dynasty promoted repopulation of devastated regions and practiced massive resettlements that moved tens of thousands of people to reclaim vast tracts of land. Reforestation was another component of the Ming agricultural reforms, and from the late fourteenth century through the fifteenth century millions of trees were planted throughout the empire; some scholars estimate that up to 1 billion trees were planted in Hongwu's reign alone. These policies had a

profound effect on the Chinese society. Increased food production led to population growth, which in turn led to the growth of Chinese cities. This increased urbanization promoted trade and commerce, as markets developed in these expanding towns and cities. The Ming rulers also promoted development of certain industries, and the manufacturing of silk, other textiles, and porcelains reached new heights. Periodic census and land surveys helped government officials to pursue more efficient governance and increased tax collection. Civil service examinations, which every civil official had to pass, ensured the existence of an efficient administration. Chinese society was divided into major social categories, and at birth every person was listed in a social group based on his or her father's occupation. To maintain their power, the Ming rulers also utilized a secret police that was dominated by eunuchs, some of whom—Wang Zhi (late fifteenth century), Liu Jin (sixteenth century), and Wei Zhongxian (early seventeenth century)—rose to the pinnacle of the Ming government.

Ming foreign policy sought to isolate China from the outside world, which the later Ming rulers perceived as a threat. Thus, the Great Wall was reinforced and expanded in the north, and free contacts with foreign merchants were prohibited in eastern and southern ports. One of the most dramatic episodes of the era took place in the early fifteenth century when the Ming rulers embarked on major maritime expansion. Led by Admiral Zheng He, the Chinese fleet, featuring some of the largest ships ever created (which were only fit for the relatively calm waters of the Indian Ocean), sailed throughout the Indian Ocean, extending the prestige of the Ming dynasty and reestablishing commercial contacts with Southeast Asian and African states. Remarkably, upon completion of the last voyage this unique fleet was scuttled and destroyed as the Ming rulers reverted to a policy of isolation. The start of the European Age of Expansion, however, meant that China became an active part of the emerging global economy. Europeans showed great demand for exquisite Chinese products and were willing to pay for them in silver. As some studies show, up to half of all silver mined in the Americas between 1527 and 1821 eventually ended up in China. In the late sixteenth century and the seventeenth century China's population almost doubled, the economy showed remarkable vibrancy, and certain

manufacturing—silk, porcelain, printing, steel, etc.—even showed signs of industrial development.

Yet despite such a thriving economy and growing mercantile society, the Ming dynasty faced economic, political, and military problems. Bitter power struggles undermined the dynasty from inside. Unlike Hongwu's fiscal restraint that had

Unlike Hongwu's fiscal restraint that had benefited the state, his successors pursued opulence and extravagance, probably best exemplified in the building of the famous Forbidden City in the fifteenth century.

benefited the state, his successors pursued opulence and extravagance, probably best exemplified in the building of the famous Forbidden City in the fifteenth century. A massive complex of over 900 buildings that hosted thousands of people, its grandeur far surpassed that of any

European palace, but such profligacy also placed great financial burden on the treasury. The social categories that Hongwu established in the fourteenth century broke down. External threats mounted as the Manchus, a Tungusic people in Manchuria, harassed Chinese borders in the north, and the Japanese and Koreans did the same in the south-east. Maintenance of a large army to face these threats and maintain domestic order placed a heavy burden on the economy; many troops, with their pay in arrears, left the ranks and either became outlaws or joined the Manchus. Tax increases only fostered discontent, and anti-tax tumults occurred in major commercial centers of the kingdom. The nature of the Ming emperorship also posed a great problem, since the rulers tended to concentrate on performing and participating in time-honored imperial ceremonies rather than on actual governance. By the seventeenth century the actual political power was largely in the hands of high court officials whose policies only precipitated crisis. In 1644 the Manchus invaded China, overthrew the Ming dynasty, and gained control of all of China.

The Qing dynasty, which the Manchus established and which ruled until 1912, retained most of the Ming government's structure. The Manchus themselves maintained a privileged status and held some high positions but retained the earlier tradition of civil examinations for officials. The reigns of Kangxi (1662–1722) and Qianlong (1736–1795) marked the height of the Qing dynasty. The Chinese emperors controlled one of the largest empires in the world that stretched from Manchuria to Tibet and claimed tribute from many states in Southeast Asia. The emperors cultivated arts and literature, pursued new agriculture improvements, and successfully dealt with foreign threats.

Japan

By the fifteenth century Japan was controlled by the Ashikaga Shogunate, which was established in 1336. Although officially led by an emperor, real power lay in the hands of shoguns (generalissimos). This period saw increased fragmentation of Japan as various daimyos, or lords, sought greater independence. Around 1450, some 250 daimyos held power in various provinces of Japan. Their increased rivalry and a dispute over shogunal succession eventually caused the Onin War, a decade-long conflict that resulted in one of the most devastating eras in Japanese history. The era of the Warring States was a period of nearly continuous military conflict and profound social and political upheaval that lasted until the early seventeenth century. It greatly weakened the central authority of the shoguns and produced a major social change, known as *gekokujo*, when men from lower strata rose to high positions. The introduction of European firearms in the mid-sixteenth century proved to be a turning point in the Japanese civil strife. Oda Nabunaga, a samurai of the lesser daimyo ranks, used this new military technology to defeat neighboring lords and extend his power to a large part of Japan including the capital of Kyoto, which

he seized in 1568. Over the next 32 years Japan experienced rapid and dynamic change as several powerful lords struggled for control of the entire country. In 1575 Nobunaga again skillfully utilized firearms to crush his opponents in the decisive Battle of Nagashino, which gave him control of eastern and northern Japan. His campaigns against Buddhist temple-fortresses that rejected his authority led to the destruction of many temples and monasteries, whose wealth in turn financed further campaigns. Nobunaga also showed himself as a skilled statesman, as he developed government machinery, standardized currency, promoted construction especially of castles to exert his authority over the countryside, and fostered trade and commerce. He turned the small seaside village of Nagasaki into an important commercial center for trade with European merchants.

In 1582 Nobunaga was assassinated by one of his retainers and was succeeded by one of his generals, Toyotomi Hideyoshi. A talented military commander, Hideyoshi played an important role in the eventual unification of Japan. In 1582 he seized the Takamatsu fortress and the Mori province it controlled and later secured the island of Kyushu in southern Japan. He conducted a massive survey of all of Japan, which his officials used to establish taxes and military quotas. Although his two invasions of Korea between 1592 and 1598 proved to be disastrous for the Japanese, by the time he died Hideyoshi left a highly centralized state that ruled over Japan. His death provoked a power struggle among several pretenders that was won by Tokugawa Ieyasu in the decisive Battle of Sekigahara in 1600.

Tokugawa's victory marked the beginning of the Tokugawa shogunate that lasted until 1868. While the emperor retained sovereign authority, the real authority and power was in the hands of the Tokugawa shoguns who ruled the country from their capital at Edo (Tokyo). They established a highly centralized government that ruled over a strictly hierarchical society divided into four social groups (court nobles, samurai, merchants, and peasants). To safeguard their authority, the shoguns suppressed any domestic or foreign threats. The latter primarily came from Europeans, who pursued trade and missionary activity in Japan. The number of Roman Catholic converts rapidly increased, and many

Starting around 1636, the shoguns put in place the so-called sakoku policies that forbade foreigners from entering the country and virtually sealed off Japan to outside influence.

of them participated in revolts against the shogun's authority such as the 1637 revolt in northern Kyushu, which was heavily Catholic. The shoguns thus came to associate Christianity with a threat to their power and took actions to fight it. Christians, largely Catholic Japanese, were persecuted, and European priests were expelled. Starting around 1636, the shoguns

put in place the so-called *sakoku* policies that forbade foreigners from entering the country and virtually sealed off Japan to outside influence. Only the port of Nagasaki was left open to the Dutch but only for a short period of time. Over the next 200 years the Tokugawa regime brought peace, stability, and economic growth to Japan.

Sub-Saharan Africa

By the mid-fifteenth century sub-Saharan Africa was a vibrant region that included both large and powerful kingdoms and smaller but flourishing societies united by family or kinship ties. The African states spanned almost the entire continent, with the kingdoms of Mali in West Africa and Songhai, Kanem-Bornu, and Hausaland in central Africa, while Ethiopia and the famous Swahili city-states prospered along the eastern coastline of Africa.

West Africa

West Africa had long served as an important trade region where caravans from North Africa and the Middle East traded with local states. The region was initially dominated by the kingdoms of Ghana and Mali, but by the fifteenth century several new states emerged. Thus, the state of Wolof gained its independence from Mali in the north, while Kantora remained under Malian influence in the south. These states usually had a well-defined government hierarchy, with a king, often elected by nobility, presiding over the state. But not all sub-Saharan peoples had formed states, and many lived in stateless societies led by family or clan elders. These societies were agrarian in nature, and the cultivation of land was the primary occupation of its members. Families helped each other in clearing land from surrounding forest, cultivating it, and gathering harvest. In Senegambia, a region between the Senegal and Gambia rivers, millet, sorghum, and yams were the staple food, supplemented with plantains, beans, fish, and small game, while in the south, along the coast of Guinea, rice played an important part in daily life. As Robert W. July, a prominent scholar of precolonial Africa noted, “life was simple, government was largely limited to the settlement of disputes by family heads or elders, the basic economy scarcely more than the production and consumption of food, social life centered on the ceremony accompanying birth, death and family alliance.”

In the fifteenth century a new powerful state, the kingdom of Benin, emerged in present-day Nigeria. Ruled by an oba (divine king), the Benin kingdom came to prominence under the leadership of the Oba Ewuare (ca. 1440–1473), who overcame tribal and village chiefs (uzama) to centralize his authority and considerably expanded his realm's borders. His successors Ozolua (1481–1504) and Esigie (1504–1517) continued his policies. At its height in the sixteenth century the kingdom of Benin controlled a vast territory between the Niger River in the east and Yoruba country in the west. In 1485 the Portuguese reached this region, and the ensuing profitable trade in spices (primarily pepper) and slaves further strengthened Benin. Its capital, Benin City, became one of the great urban centers in Africa, a city of 25 miles in circumference protected by walls and intersected by numerous streets and avenues. The city was divided into two sections, the larger for the town's residents and the smaller for the elite and royalty. As trade flourished so did the arts, and the Benin craftsmen refined their skills with copper

and brass, producing elaborate pieces of art. These Benin bronzes, magnificent in their craftsmanship, vividly conveyed the oba's power and authority and also recorded tradition and folk tales. Sadly, nothing remains today of this glorious city. In 1897 a British expeditionary force led by Admiral Sir Harry Rawson conquered and destroyed the city and much of its famous buildings and treasured art.

To the north of Benin lay Songhai, a successor state of Ghana and Mali. Songhai was the last of the three great empires of the western Sudan. It was founded under the leadership of Sonni Ali (r. 1464–1492) when Songhai authority extended to almost the entire basin of the Niger River, including the famous Timbuktu. Sonni Ali showed himself as a talented military and political leader who divided his empire into provinces, established a navy (led by a commander known as the hi-koy), and promoted trade. Upon his death a power struggle between his successors ensued, which ended in the victory of Muhammad Ture, a devout Muslim of Soninke origin, who soon took the title “Askiya” (Great Leader). Askiya Muhammad I Ture (r. 1493–1538) completed the expansionist and administrative policies of his predecessor. He conducted wide-ranging campaigns that brought new regions under Songhai authority. A convert to Islam, he made a hajj (pilgrimage) to Mecca and used Islam to unite his far-flung empire. After his successful wars of expansion, Ture reorganized the administrative system set up by Sonni Ali. Ture divided the empire into four vice royalties, each under a viceroy or governor usually chosen from the royal family or a trusted servant. He established a council of ministers and replaced local Songhai officials with more efficient Arab ones. Under the leadership of Muhammad Ture, Songhai enjoyed an economic prosperity, and visitors remarked on its abundant food supplies and vibrant trade. European and North African commodities (clothes, perfumes, copperware, glass, etc.) were in high demand and were delivered by European and Muslim merchants. Following their expulsion from Spain in 1492 a large number of Jews came to Songhai, where they quickly became involved in trade. Muhammad Ture

Muhammad Ture revived Timbuktu as an important educational and Islamic center, and its reputation soon drew many Muslim scholars and clerics for educational pursuits as well as for trade.

revived Timbuktu as an important educational and Islamic center, and its reputation soon drew many Muslim scholars and clerics for educational pursuits as well as for trade. In 1513 Leo Africanus visited the town and was struck by “a great store of doctors, judges, priests, and other learned men that are bountifully maintained at the King's court.” After a 35-year reign the

aged Muhammad Ture, known as Askiya the Great to later generations, was deposed by his children in 1528. His successors failed to live up to his legacy, and the Songhai state quickly declined amid internal dissent and political turmoil before being finally destroyed by the invasion of the Moroccan sultan al-Mansur in 1591. In the aftermath the once-great empire split into numerous small kingdoms.

To the east of Songhai prospered the kingdom of Kanem-Bornu. By the fifteenth century the state of Kanem, founded by the Kanuri, a mixture of people from south of the Sahara and Berbers from the north,

existed already for some 600 years. However, in the mid-1400s the weakened Kanem was absorbed by the rising power of the Bornu state, leading to the establishment of the powerful kingdom of Kanem-Bornu. Throughout the sixteenth century the kingdom rapidly expanded under a succession of able mais (kings), the greatest of whom was Idris Alawma (r. ca. 1571–1603). His victorious campaigns greatly expanded the kingdom's territory, while shrewd domestic policies resulted in a centralized state administration and profitable trade. A devout Muslim, Idris Alawma built mosques at his capital city of N'gazargamu and introduced Islamic law in place of African customary laws. However, as often happens, Alawma's successors proved to be less capable, and the kingdom gradually declined and was later absorbed into the French West African empire.

East Africa

In East Africa, the Christian kingdom of Ethiopia along the Horn of Africa enjoyed a revival under the ruling Solomonid dynasty, which controlled a vast territory from the Red Sea port city of Massawa in the north (in present-day Eritria) south to Shoa in the central highlands. Under the reign of Amda Seyon (r. 1312–1342) and his successors Ethiopia embarked on a major campaign of expansion, which brought it into a prolonged conflict with the neighboring Muslim states. The Solomonid rulers initially enjoyed a series of military successes that ensured the Christian state's dominance in the region. This period of political and economic stability led to a religious and literary revitalization as well. Ethiopian literature was enriched by numerous translations of religious texts, including the *Senkessar* (a compilation of the lives of Christian saints) and the *Metshafa Berhan* (*Book of Light*) as well as new royal chronicles, notably the *Kebra Nagast* (*Glory of the Kings*), which claimed that Ethiopian royal descent could be traced to King Solomon and the Queen of Sheba of the Old Testament.

The political situation, however, changed in the early sixteenth century. Ahmad ibn Ibrahim (otherwise known as Gran, “the left-handed”), the ruler of Adal, declared a full-scale war on Ethiopia and launched a series of campaigns that between 1529 and 1543 spread death and destruction in Ethiopia. Continued military setbacks forced King Galawdewos (r. 1540–1559) to seek help in Europe, especially from the Portuguese. With the help of a small but well-armed Portuguese contingent, the Ethiopian forces drove the Muslims out of the central highlands and later conducted successful campaigns throughout the 1550s, 1560s, and 1570s. Aside from immediate devastation, this long conflict also changed the dynamics in the southern highlands of Ethiopia, where the Oromo (also known as the Galla) tribes of pastoralists began to infiltrate from the grasslands of the south and to settle. The Oromo arrival altered the demographic picture of highland Ethiopia and later profoundly affected Ethiopian politics.

In the seventeenth and eighteenth centuries, Ethiopia was involved in continued warfare against the Muslim states in the south and the Ottoman expansion in the north as well as the neighboring pastoral

tribes. The ancient Ethiopian Orthodox Tewahedo Church also faced a number of challenges. Continued warfare devastated many churches and destroyed literary and artistic treasures. Close contacts with Portugal inevitably led to Jesuit missionary activity, which the Ethiopian Church perceived as a threat. Theological disputes between the Jesuits and Ethiopian clergy regarding whether Christ had one totally unified (Tewahedo) divine nature or two separate divine and human natures later led to the former's expulsion (and increased hostility to foreigners), but they also prompted emperors Fasiladas (r. 1632–1667) and Yo-hannes (r. 1667–1682) to organize several councils of church leaders to discuss theological doctrines. These debates resulted in protracted religious and political schism in the kingdom. The mid-eighteenth century, however, saw the rise of Mentewwab, one of the most remarkable women rulers of this age. Ruling as a *yetégé* (empress) during the reigns of emperors Iyasu (r. 1730–1755) and Iyoas (r. 1755–1769), Mentewwab provided firm guidance to the state and succeeded in reviving it. Arts and literature flourished, while Mentewwab's patronage of churches led to the construction of the magnificent Débré Séhay Qwesqwam (Church of Virgin Mary), which influenced church architecture for several generations. The year 1769, however, marked a turning point in Ethiopian history. After Mentewwab was forced into exile and Emperor Iyoas was assassinated, the kingdom fell into a long Era of the Judges (the *Zemene Mesafint*, 1769–1855, so-called because of its reference to the biblical Book of Judges that recorded the troubled political time of disunity for the early Israelites) when emperors changed in rapid succession as a result of bitter struggles between nobles, the most powerful of them being the Oromo nobles who dominated the Ethiopian kingdom until the 1850s.

Farther south in coastal eastern Africa existed the Swahili city-states that developed a reputation for commercial prosperity. The cities of Mogadishu, Mombasa, Kilwa, and Sofala maintained trade contacts throughout the Indian Ocean, the Middle East, and Africa and reached their peak of development in the fourteenth through the fifteenth centuries. Fiercely competitive, the cities vied for political and commercial hegemony, in the process creating a unique cultural legacy. They embraced religious syncretism, as represented in festivals and competitive celebrations that combined local and Islamic traditions. The Swahili ritual calendar combined the Persian solar calendar for local rituals, farming, and navigation with the Arabic lunar calendar for religious celebrations.

The Portuguese soon embarked on building their maritime empire in the Indian Ocean, and the Swahili city-states were ill-prepared to defend themselves.

The arrival of the Portuguese fleet led by Vasco da Gama in 1498 marked a turning point in the Swahili cities' history. The Portuguese soon embarked on building their maritime empire in the Indian Ocean, and the Swahili city-states

were ill-prepared to defend themselves. But the European occupation proved to be fleeting, as thousands of residents left their cities, as in the case of the city of Kilwa, which the Portuguese abandoned in 1512.

Furthermore, after their triumph over a Muslim and Indian coalition in a naval battle at Diu in 1509, the Portuguese accorded low priority to the East African coast and concentrated their efforts on India and Arabia. The initial Portuguese withdrawal from East Africa created a political vacuum, and many Swahili city-states were plunged into a period of turmoil as their overseas commerce collapsed. Some towns, such as Kilwa and Mombasa, turned inward and developed commercial ties with the hinterlands. By the end of the sixteenth century the Portuguese dominance in the Indian Ocean declined, following the kingdom's disastrous invasion of Morocco in 1578 and the Spanish takeover of Portugal in 1580.

As Portuguese garrisons in Africa were drawn down—at least for the time being—the Swahili cities saw the arrival of a new power. Following their conquest of Egypt in 1516–1519, the Ottoman Turks had gradually expanded their influence to Arabia and the Red Sea. Their struggle against the Portuguese posed them as potential allies to Swahili towns, which now supported Turkish efforts in the Indian Ocean. Throughout the 1580s the appearance of Ottoman forces caused a series of revolts in Swahili towns, which the Portuguese, again aware of the importance of East Africa, now subdued. Having reestablished their dominance on the East African coast, the Portuguese made Mombasa the center of their new and reinforced presence, which endured for almost four decades. By the mid-seventeenth century the Portuguese faced a new threat when the Omani Arabs became determined to drive them out of the northern Indian Ocean. In 1661 an Omani raid sacked Mombasa, ending Portuguese power on the coast north of Mozambique. While individual Swahili towns remained largely independent, Omani suzerainty, which persisted for the next 200 years, led to an upsurge in trade as well as a profound Arab influence in religion, law, commerce, architecture, dress, and vocabulary.

Southern Africa experienced a history that was distinct from West and East Africa. Until the arrival of the Portuguese in the fifteenth century, southern Africa developed outside of direct influence of the Mediterranean cultures and the Islamic world. Its political and religious life centered around several polities that developed well before 1450. The most important of these was the kingdom of Zimbabwe, which rose to prominence in the thirteenth century and flourished until the fifteenth century. Its capital was Great Zimbabwe, which extended over 60 acres and included a formidable edifice, known as the Great Enclosure, consisting of a fortified enclosure with walls as high as 36 feet. The state's wealth rested on the area's rich gold-bearing belt, resulting in a profitable gold trade with the eastern coast. In the mid-fifteenth century the kingdom of Zimbabwe rapidly declined, perhaps because of soil exhaustion and overpopulation. By the time the Portuguese reached East Africa, Great Zimbabwe and most of the kingdom had been abandoned. Instead two new states emerged, the kingdom of Mutapa, stretching between the Zambezi and Limpopo rivers in the north, and the kingdom of Butua in the south. Both states developed in the tradition of Zimbabwe until they were taken over by the Rozwi empire.

The Americas

At dawn on October 12, 1492, Rodrigo de Triana, a sailor on board the *Pinta*, sighted a land in the distance. Thus began European exploration of unknown land in the west. In 1501–1502 the Florentine explorer Amerigo Vespucci explored this new land and, convinced that it was a new world, published accounts of his voyage. Thereafter European cartographers labeled this new land as “Amerigo’s land,” or America. Initially applied only to South America, the term was later used to refer to the entire landmass located in the Western Hemisphere. Yet the “New World” was a European invention, since these lands had been long “discovered” by people who created several major civilizations here by the time Europeans arrived. America’s varied terrain and climate shaped these civilizations. The vast expanse of North America as well as the enormous Amazon basin, Mesoamerica (Mexico and Central America), and the western coastline of South America saw the rise of sophisticated sedentary societies and civilizations. The Hohokam was one of the major cultures in the present-day American Southwest, where Native Americans practiced agriculture in a series of small villages along the Salt and Gila rivers of present-day Phoenix, Arizona. Despite lacking advanced engineering tools, the Hohokam developed a remarkable irrigation system that allowed them to cultivate maize, beans, and squash in a desert environment. The Iroquois League of Nations, or “People of the Long House,” had developed a unique social and political structure that contributed to political thinking during the development of the U.S. government. The Mississippian culture flourished between the thirteenth and sixteenth centuries as the people practiced sophisticated agriculture and developed a complex social organization. The Mississippian culture created vibrant communities that featured the largest earthworks in North America north of Mexico, most notably at Cahokia outside present-day East St. Louis, Illinois, where the massive Monks Mound—some 100 feet high and over 770 feet wide—rivalled Egyptian pyramids and the great temples of the Aztecs. The Cahokia complex contains dozens of mounds whose location and alignment reveal a profound understanding of astronomy. Scholars estimate that at its peak Cahokia may have had a population up to 30,000–40,000 people, a number not matched by any city in the present-day United States until the late eighteenth century.

Major Colonial Conflicts	
1655	Dutch colonists from New Netherland conquer New Sweden
1664	British seize New Netherland
1675–1676	Bacon’s Rebellion in Virginia; King Philip’s War in New England
1689–1713	King William’s War
1702–1713	Queen Anne’s War
1740–1748	King George’s War
1756–1763	Seven Years’ War (French and Indian War)

Europeans explored North America starting with John Cabot's voyage in 1497. While the English and French explored in the present-day northeastern United States and Canada, the Spaniards claimed territories in the south, following Juan Ponce de Leon's landing in Florida in 1513. By the early seventeenth century the French had established the first permanent colony at Quebec (in present-day Canada), while the English built a colony at Jamestown (Virginia). In 1609 Henry Hudson claimed part of North America for the United Provinces (the future Netherlands), and Dutch outposts soon appeared, notably New Amsterdam in 1624. These colonies were established as private enterprises that employed European migrants fleeing from civil and religious disturbances that plagued seventeenth-century Europe. Despite failed early attempts, England rapidly gained ascendancy over most of eastern North America, where by the mid-eighteenth century the English created 13 colonies. France developed a vast colony, New France, in present-day Canada but was forced to cede it to the English following its disastrous performance in the Seven Years' War (1756-1763). The Native Americans played an integral part in this colonization. In many instances their collaboration and help ensured the survival and success of European colonies. The natives were also actively involved in colonial conflicts that developed among the English, the Dutch, and the French. Each side allied itself with native tribes (who often fought on both sides) and used them to conduct proxy wars against each other. But these wars and, most important, diseases that Europeans introduced struck heavily among the native tribes, drastically reducing their numbers and their ability to protect their lands.

The Aztecs, who founded their capital of Tenochtitlan around 1325, created a vast empire that exerted its influence over most of central Mexico. The Aztec state was geared for war, and a strong standing army lay at its heart. War was one of the major components of the Aztec religion, since the Aztecs believed that to sustain life on earth they had to appease the gods by providing them with human blood. Thus, mass sacrifices were routinely practiced and naturally required a constant supply of victims. The Aztecs conducted far-ranging campaigns to seize prisoners throughout the region and used human sacrifice as an instrument of state terror that kept dozens of local tribes in subjugation. This brutal practice proved to be of great consequence since these conquered tribes were willing to support the newly arrived Spanish conquistadors against their oppressors, a key factor in the fall of the Aztec empire in the sixteenth century. The Aztecs presided over a vibrant culture whose achievements often eclipsed those of Europe. Thus, the Aztec capital city of Tenochtitlan probably had at least 500,000 residents at a time when no European city even remotely approached this number. The Spaniards were stunned by Tenochtitlan's wide and clean streets, numerous parks, and sophisticated aqueduct networks that delivered fresh water and maintained fountains. The sewage drains, virtually unheard of in contemporary Europe, took human refuse out of a city that was maintained clean and safe by special cleaning and firefighting brigades. The city skyline was dominated by tall and impressive temples

built in the shape of pyramids, the likes of which no European had seen prior to that time.

The powerful Aztec empire collapsed following the arrival of the Spanish adventurer Hernando Cortés in 1519. In less than two years Cortés completely demolished the Aztec state and razed to the ground parts of its capital. His success can be explained by a combination of factors. In hindsight we know that the timing of the Spanish arrival was rather crucial to their eventual success. Europeans entered the Aztec empire when its inhabitants were preoccupied with harvesting and were not prepared for war. The highly hierarchical society, in which all authority was concentrated in the hands of the Aztec ruler, further played into Spanish hands since Cortés' bold act of taking Moctezuma (Montezuma), the Aztec ruler, had great influence over the Aztec society. The most decisive factors in the Aztec collapse, however, were Spanish success in securing alliances with local tribes, who were happy to see their oppressors gone, and the spread of European diseases, which devastated Aztec society. By the mid-sixteenth century the Spaniards exerted their influence over much of present-day Mexico and gradually expanded their influence to the neighboring regions.

Like the Aztec empire, the Inca empire, which rose to prominence in the fifteenth century on the west coast of South America, was also a highly centralized state where all power belonged to the supreme leader, the inca. Under the leadership of Pachacuti Inca (r. 1438?–1471?) and his son Topa Inca (r. 1471–1493), the Incas embarked on a rapid expansion that extended their realm from present-day Colombia in the north to the Maule River (in present-day Chile) in the south. By the mid-sixteenth century some 16 million people lived in this sprawling empire. Unlike the Aztecs who ruled by state terror, the Incas practiced imperial colonization and integration, best represented in the policy of forced resettlement, or *mitima*. The conquered people were often relocated to other parts of the empire to encourage their loyalty to the state, to compel acceptance of the Inca language (Quechua) and beliefs, and to practice better utilization of land resources. The Incas developed a sophisticated network of roads that facilitated trade and communications as well as allowed rapid army movements. The Inca architecture was characterized by highly skilled masonry that featured precisely cut and shaped stones closely fitted without mortar. Yet centralization of the society, in which the state regulated almost all aspects of life,

also meant that the majority of the people were denied choice and initiative, an important factor when considering the Inca collapse.

In 1532 the Spanish adventurer Francisco Pizarro and his small band of less than 200 men reached this powerful empire. As with Cortés, Pizarro's timing could not have been better. The Inca em-

In 1532 the Spanish adventurer Francisco Pizarro and his small band of less than 200 men reached this powerful empire. As with Cortés, Pizarro's timing could not have been better.

pire was just emerging from a bitter dynastic struggle that led to civil strife. In 1527 Inca Huyana Capac died without naming his heir, and his sons Huascar and Atahualpa fought a destructive five-year-long civil

war that ended with Atahualpa's victory. Overconfident of his power, Atahualpa agreed to meet the Spaniards at the place of their choosing, where he was captured by Pizarro's men who knew that by controlling Atahualpa they would control the Inca state. Despite the Incan people's fulfilling of the Spanish ransom demand and filling three large rooms with gold and silver, the Spanish executed Atahualpa in July 1533 and embarked on a conquest of his empire, which was largely completed by the end of the sixteenth century. For the next 250 years South America remained part of the Spanish empire.

Europe

The period between 1450 and 1770 saw remarkable changes in Europe. The Age of Renaissance produced an intellectual movement known as humanism that asserted human dignity and individualism and sought to understand human nature. Renaissance writers such as Petrarch and Boccaccio and artists such as Donatello, Michelangelo, Brunelleschi, Bernini, and da Vinci revolutionized the arts and sciences and produced a bewildering wealth and diversity of European culture. Outside Italy, cultural change accelerated in France, the Netherlands, and Germany where an international Gothic style flourished, and artists such as Jan van Eyck, Hieronymus Bosch, Albrecht Durer, and Jean Clouet drew their inspiration from Italian Renaissance art. Gutenberg's printing press, perfected by 1455 but centuries after the Koreans and Chinese experimented with movable type printing presses, had a profound impact on the dissemination of ideas and proliferation of art.

The sixteenth century witnessed the start of the Reformation that shook the political and religious foundations of Europe. At the same time, as Europeans discovered new routes to Asia and learned about the Americas, we see the emergence of European commercial and political influence on a global scale. It was the wealth and power of Asia that inspired Europeans to travel during what we now call the Age of European Exploration. Starting with early Portuguese and Spanish maritime exploration for new routes to Asia, Europeans began to utilize new technological innovations to obtain wealth and influence. They sought to reduce their reliance upon Muslim traders (the people through whom they obtained the goods and spices of the East) and profit from new direct routes to Asia. After all, Columbus sought a new western route to India, not a new land that we now know as the Americas. Yet after the discovery of the Americas, Europeans fully employed its vast riches (primarily silver) to buy their way into Asian markets. By the eighteenth century the epicenter of the emergent global economy became the Atlantic world, where Europeans developed a triangular trade among Europe, Africa, and the Americas. In its simplest form, ships laden with European manufactures regularly sailed to West Africa, where they traded goods for slaves who were then transported and traded for colonial products in the Americas before the ships returned to their home port.

Several factors motivated the expansion of Europe. To some degree this process was an expression of curiosity and a desire to learn more

about the world. The desire to spread Christianity and “save the souls” also greatly contributed to this process. But economic and political considerations were the most important factors in the expansion, as the spice trade with Asia promised vast profits that a state could use to strengthen itself vis-à-vis its neighbors. The Spanish conquistador Bernal Díaz del Castillo probably summed it up best when he said that his motives for exploration were “to serve God and His Majesty, to give light to those who were in darkness and to grow rich as all men desire to do.” The European exploration proved to be successful because of remarkable technological developments achieved in this period. Firearms, stronger and sturdier ships capable of carrying cannons, and new military tactics helped Europeans as they encountered many indigenous cultures. In addition, Europeans successfully utilized technological advances of other cultures, such as the magnetic compass from China and astrolabe and portolan charts from the Islamic world.

These advances allowed Europeans to extend their authority to parts of the Americas, coastal Africa, and South and Southeast Asia. In the process they destroyed or severely weakened indigenous populations, set up colonial administrations, and developed seaborne trading empires that gradually ensured Europe’s emerging global preeminence. Spain dominated Central and South America, and the Portuguese controlled Brazil, the western coastline of Africa, and coastal parts of India and Indonesia. England and France extended their influence to North America and India, while the small Netherlands created one of the largest trading empires in India, Southeast Asia, and the Americas. The influx of gold and silver mined in the Americas had a profound impact on Europe as the Spanish empire, the primary benefactor of American

colonization, enjoyed the “Golden Century” of blossoming arts, architecture, and literature. Yet abundance of bullion also caused dramatic inflation and price increases that adversely affected Europe.

Religiously, Europe also experienced a major transformation. In 1500 Europe was largely Catholic, with only parts of southeastern Europe practicing Eastern Orthodox Christianity. By 1648 its religious map completely changed as Scandinavia, most of Germany, Switzerland, Scotland, and

In 1500 Europe was largely Catholic, with only parts of southeastern Europe practicing Eastern Orthodox Christianity.

By 1648 its religious map completely changed as Scandinavia, most of Germany, Switzerland, Scotland, and England embraced Protestantism.

England embraced Protestantism. The power of the Catholic Church declined, although the Counter-Reformation ensured Catholic dominance in France, Spain, Italy, and parts of the Holy Roman Empire. Concurrent with the Protestant Reformation, the Catholic Church underwent its own reform movement from within. The Council of Trent (1545–1563) sought to reform the Church but also encouraged orthodoxy enforced by a court of Inquisition. The Reformation had a profound impact on political life in Europe, and oftentimes religion was difficult to distinguish from politics. England’s break with the Catholic Church had much to do with both Protestant influence and King Henry VIII’s desire to ensure the stability of his dynasty. Subsequent religious strife in England led

to an acute political crisis as the country plunged into civil war in the mid-seventeenth century. Most of Europe experienced political turmoil caused by religious ferment. In France this religious conflict is most famously represented by the St. Bartholomew's Day Massacre (1572), a purge that claimed thousands of Protestant lives and began a 17-year-long conflict. Yet another manifestation of the rift between Catholics and Protestants was the Thirty Years' War (1618–1648) that devastated Germany, killing millions and fragmenting the region.

This same period also witnessed a profound social change as serfdom—a condition in which a tenant farmer was bound to a hereditary plot of land and to the will of his lord—was consolidated in much of central and eastern Europe. The bubonic plague of the fourteenth century had a great effect on western Europe's manorial system, and by the fifteenth century peasants there gained greater freedom and successfully resisted attempts to reimpose traditional manorial relationships on them. Their brethren in central and eastern Europe, however, shared a different situation, and most peasants in eastern and central Europe lost their freedom and became serfs by the mid-seventeenth century. In Poland nobles gained complete control over their peasants in 1574, while Russia enserfed its peasants by 1649, and Prussia did so in 1653. The consolidation of serfdom was further facilitated by a population growth that sharply increased prices for agricultural commodities, giving the nobles powerful economic incentives to strengthen their authority over peasants and increase the productivity of their estates.

The seventeenth and eighteenth centuries produced a remarkable change in the European worldview. The foremost cause of the change was the Scientific Revolution. Scholars refashioned long-held beliefs about the universe while new discoveries, many of them long anticipated by or even borrowed from Muslim scientists of an earlier age, revolutionized understanding of astronomy, physics, biology, medicine, and other fields. Eventually some Europeans began to change the way they viewed the natural world and humanity's place in it. The Enlightenment, as this eighteenth-century movement became known, embraced the idea that the methods of natural science could and should be applied to examine and understand all aspects of life. Emphasizing reason, rationalism, and skepticism, the philosophes sought to discover laws governing human society and embraced the notion of progress. They believed that through the scientific method, it was possible to create better societies and better people, a belief that underlay many of the improvements that took place in the late eighteenth century and the nineteenth century.

Politically, the sixteenth and seventeenth centuries saw an unprecedented spate of wars and revolutions in Europe. Looking at the seventeenth century alone, one is struck by the fact that only two years (1670 and 1682) in an entire century were without a war between the European states. Looking at individual states, we see that between 1618 and 1678 the Dutch Republic was at peace for only 14 years, France for 11 years, and Spain for only 3 years! These wars produced unparalleled political, social, and religious changes. The prolonged Hundred Years' War ended in 1453 with a victory for France, while the loss of most of

England's continental possessions profoundly affected the development of that country for the next 500 years. In 1494 France attempted to expand its power to rich Italian states but became embroiled in a long conflict with Spain. By the end of the Italian Wars in 1559, Habsburg Spain had been established as the premier power of Europe, while the Italian states, which had wielded so much power during the Renaissance, were from now on reduced to second- and third-rate powers. Defeated in this conflict, France was plunged into a long political and religious strife that came to an end in 1589. In the meantime, England successfully dealt with the Spanish threat in 1588 and supported the Dutch rebels, who in 1648 secured their independence from Spain after an 80-year-long struggle. These conflicts sapped Spanish resources, and by the late seventeenth century Spain had entered a long period of decline. In the mid-sixteenth century Germany saw the beginning of religious conflict that continued for almost a hundred years. The Thirty Years' War produced devastation on an unparalleled scale in Germany, which lost up to a quarter of its population and saw entire regions laid to waste. Yet this war also marked the rise of France as a great power on the continent, and European states spent subsequent decades seeking to contain the French hegemony.

These wars significantly differed from earlier conflicts. The arrival of gunpowder from Asia profoundly altered both the nature of war and popular attitudes toward it. Chivalric notions disappeared, as did medieval castles that could no longer resist artillery sieges. Military tactics favored infantry over cavalry, leading to the disappearance of armored knight cavalry that had dominated European battlefields for generations. The size of armies gradually increased and, by the early eighteenth century they routinely numbered 40,000 to 50,000 men. Because large armies, armed with cannon and firearms, were prohibitively expensive, they could be maintained only by strong states, forcing governments to reorganize their administrations to ensure more effective governance and tax collection.

The seventeenth century also witnessed the development of absolutism. This process was best exemplified in France, which developed a strong highly centralized monarchy as the result of the policies of kings Henry IV (r. 1589–1610), Louis XIII (r. 1610–1643), and Louis XIV (r. 1643–1715). Under the leadership of Cardinal Armand Jean du Plessis de Richelieu (r. 1624–1642), the French monarchy embarked on total subordination of all groups and institutions to its authority. By the late seventeenth century the administrative and political reforms created a massive state bureaucracy (presided over by a king), although its reach and actual ability to impose its will in the provinces was severely limited by logistics and tradition. Louis XIV weakened the power of the highest nobles by excluding them from his councils and restricting their role in the government. Instead, he promoted the men from the upper middle class or the recently ennobled who formed the new “nobility of the robe” (because of the long official robes many of them wore) who provided a balance to the power of the great nobles.

In the rest of Europe, Spain, after experiencing its golden age in the sixteenth century, then suffered a long decline. The lack of a strong

middle class, agricultural stagnation, and the failure to promote manufacturing enterprises and maintain commercial competitiveness, together with prolonged conflicts that drained treasure and increasing inflation, reduced Spain to a second-rate status by 1715. England fell into disarray soon after Queen Elizabeth's reign (r. 1558–1603), often described as a golden era in English history. Her successors, James I and then Charles I, struggled against Puritan-dominated Parliament. Ultimately Oliver Cromwell led the Puritans to victory in the English Civil War, overthrowing Charles and establishing a Puritan Commonwealth. By 1660, however, the monarchy was restored and, by 1688, was turned into a constitutional monarchy. In central Europe the Holy Roman Empire's power weakened following the religious conflicts of the sixteenth and seventeenth centuries as well as a prolonged struggle against the Ottoman empire. Yet these conflicts also facilitated the rise of a new power in central Europe. By the mid-eighteenth century under the capable leadership of several rulers, the small principality of Brandenburg, which was ravaged by foreign armies in the Thirty Years' War, turned into a premier power that changed the balance of power on the continent.

Simultaneously, Muscovite Russia rapidly expanded into eastern Eurasia, reaching the Pacific Ocean by 1648. The rise of Russia is one of the most important events in world history, but categorizing this process remains a challenge for world historians. Is Russia a civilization all its own or part of a slightly larger eastern European civilization? Should it be discussed, as is commonly the case in European history, as part of Europe even though for much of its history (until the seventeenth century) it played a trivial part in it? Between 1450 and 1750 the Russian state experienced a major transformation as it freed itself from Mongol overlordship and embarked on a steady process of expansion that brought it to the shores of the

Pacific Ocean in the 1650s. This process was unusual in the context of European history. At a time when some western European states were laying the foundation to their nation-states, Russian territorial expansion created a multinational empire that would be both its strength and its weakness in the subsequent centuries. In the seventeenth and eighteenth centuries Russian development was both similar

and atypical of European experience. Like many European states, Russia followed the path of centralization and absolutism as its tsars asserted the power of the central authority. During the reign of Peter the Great (r. 1682–1725), Russia underwent a profound social, political, and economic transformation that established it as one of the dominant powers in Europe. Petrine reforms established a Western-style regular army and navy, built an imperial infrastructure, and thoroughly reorganized the bureaucracy and government. In 1703 Peter transferred the Russian capital from Moscow to a new city, St. Petersburg, that was built from scratch on the swampy shores of the Baltic Sea. Peter's reforms created a conflict between the Westernization impetus that he introduced and

At a time when some western European states were laying the foundation to their nation-states, Russian territorial expansion created a multinational empire that would be both its strength and its weakness in the subsequent centuries.

the traditional way of life that preceded him, but they also transformed Russia, which by the mid-eighteenth century emerged as one of the leading powers in Europe.

Thus, between 1450 and 1750 the world underwent profound transformations. The transoceanic voyages of exploration and trade had bridged the Western Hemisphere and the Eastern Hemisphere, launching the new phase of global interaction in humanity's history. In this new environment, traditional political, economic, and social philosophies and organizations became increasingly out of place. The world's regions had different experiences in adjusting to the new international system that was increasingly shaped by the Europeans. The new economic realities also produced important political, cultural, and social changes. A shift in international trade routes had adverse effects on much of the Islamic world. The globalized trade and transportation brought vast migrations. Millions of Europeans left the Old World in search of better economic opportunities or religious freedoms, carrying with them the seeds of "New Europes" that they planted on the shores of North and South America and Australia. Meanwhile, Asia was on the move, and the Ottoman, Safavid, Mughal, and Chinese conquests and subsequent government policies displaced millions of people. The rise of the middle class proved to be a decisive factor in Europe, where the struggle for political authority eventually resulted in major political transformations in England, the Netherlands, and France that advocated for new political philosophies and introduced new political bodies. Furthermore, in the early eighteenth century a combination of technological improvements, political circumstances, and innovations in economic organization produced a dramatic transformation in economic productivity, the Industrial Revolution. Although these political and economic revolutions began in Europe, they ultimately affected people all over the world.

Environment and Population

The world population rapidly increased between 1450 and 1750, but a precise number of the people then living in the world is difficult to establish. The first authoritative statistics in Europe are available only from the early nineteenth century, with Britain holding the first real census in 1801. Although China had conducted censuses longer than any other country in the world, the resulting data are open to question. Yet despite such challenges, some general conclusions can be made. Most scholars agree that around 1400 the world's population was between 350 million and 400 million, and by 1800 it doubled to about 700 million to 750 million. Some areas saw major growth (e.g., China and Europe), while others saw spectacular declines, most notably the indigenous populations of the Americas. This was a remarkable increase considering that in the preceding centuries human population tended to double every 2,000 years.

Humans were not uniformly spread around the world, leading some scholars to identify 76 civilizations and cultures around the world in 1500, ranging from primitive gatherers and fishermen to sophisticated

World Population by Region (in millions), 1400–1800 (Based on R. Biraben, "Essai sur l'évolution du nombre des hommes," Population 34 (1979): 16)

societies that the great French historian Fernand Braudel described as “dense civilizations.” The 13 “dense civilizations” lived in densely populated areas around the world, notably Europe, the Near East, India, China, and Japan. By 1600 the population density (number of people living per unit area) averaged between 76 to 95 inhabitants per square mile (28 and 35 inhabitants per square kilometer). This figure has increased today to about 119 per square mile or 44 per square kilometer worldwide, but in 1600 some regions were more densely populated than others. Thus, in Germany population density varied depending on a region, with Württemberg being the most populous area in the early sixteenth century. Population density is an important factor in understanding the historical development of a given region or country. Higher populations pose greater challenges, as finite resources had to be shared by the members of society. In 1709 Daniel Defoe estimated that 3 acres (1.2 hectares) of good land or 4 acres (1.6 hectares) of average land were necessary to support one man. Yet there was only so much land to go around, so as the population swelled, social (and political) tensions increased as well. Thus, the populous Württemberg was one of the best places for recruitment of mercenary Landsknechte (country servants), mercenary soldiers who had no other prospects in their villages. In the sixteenth and seventeenth centuries there was a

Writing in 1771, Louis-Sébastien Mercier, a keen-eyed observer of French society, noted that “the husbands themselves take care in their ruptures to keep from adding a child to the household.”

massive emigration from overpopulated France and Spain that played an important role in their colonial expansions. The problem of overpopulation also contributed to the deliberate birth control that became rather prominent in Europe by the late eighteenth century. Writing in 1771, Louis-Sébastien Mercier, a keen-eyed

observer of French society, noted that “the husbands themselves take care in their ruptures to keep from adding a child to the household.”

By the end of the eighteenth century several million Europeans had migrated to the Americas, Africa, and Asia. From the 1580s to 1800 some 750,000 Spaniards reached Spanish America. By 1700 the British Americas was the home to around 270,000 persons of British ancestry, while another quarter million would arrive between 1700 and 1775. Many of the early settlers were forced to leave Europe as a result of the “price revolution,” which was caused by the influx of New World silver. The availability of silver in European trade networks inflated prices while wages remained stagnant, which worsened the economic condition of many Europeans who were forced to live at the margins of society and thus looked for new opportunity in the newly discovered lands. They were usually enticed by specific incentives, such as large tracts of land offered to any who would come to North America and agree to become indentured laborers and work for a specific period in exchange for transoceanic passage. In the mid-seventeenth century a new group of settlers began to arrive from Europe to North America. The Puritans left their homeland for their own religious freedom, and many of them were wealthier and better educated than the first wave of European migrants.

Just as Europeans expanded into the Americas and other parts of the world, Asia also experienced major human migrations. Yet unlike European migration, Asian migration largely occurred overland and did not result in catastrophic demographic declines. This was because migrations took place within a larger Asian society that had developed immunity to each other's diseases. Also, much of Asian migration was caused by nomadic conquerors who had limited experience in sedentary life and were usually assimilated by the peoples they defeated. The Mughals, of mixed Mongol and Turkish background, rose to prominence in the early sixteenth century when they conquered northern India. Their conquests led to the Muslim migration from Afghanistan, Iran, and central Asia to the Mughal court, which eventually encouraged a cultural syncretism and the mixing of groups. In the early 1600s during the reign of the Mughal emperor Akbar, the population of India probably reached 150 million, far more than in all of the European states taken together. In Iran the rise of the Safavid dynasty in the early 1500s led to the establishment of a powerful state that rivaled both the Ottoman and Mughal empires. Culturally of Turkish background, the Safavids embraced Iranian culture and practiced a policy of forced migrations. Thus, under Shah Abbas I thousands of men and women from Georgia and Armenia were forcibly removed from their homes and resettled in Iran, where they helped develop agriculture and trade and also formed the core of the modernized Safavid armies.

In China, the Mongol invasions of the thirteenth century devastated the country and reduced its population. However, the Mongol Yuan dynasty, which ruled China for a century, and the Ming dynasty that replaced it also brought stability and order to the country. By 1600 China was flourishing and probably contained up to one-fifth of the world's population. In the mid-seventeenth century the Chinese throne fell once more to foreigners. The last Ming emperor, Zhu Youjian, committed suicide in 1644 after Chinese rebels captured Beijing. A Chinese general, Wu Sangui, invited Manchu forces in to liberate Beijing and put down the rebellion, perhaps not the wisest decision. The Manchus stayed to rule as the Qing dynasty. The earlier rebellions, followed by resistance to Qing rule, combined with epidemics and natural disasters to produce a temporary decline in China's population, which quickly rebounded under the new Qing dynasty. Pacification and expansion combined with a spate of good weather to allow an unsustainable surge in population, leading inevitably to overpopulation. This resulted in massive internal migrations to and colonization of Mongolia, eastern Turkestan (present-day Xinjiang), Tibet, and southeastern Siberia by the eighteenth century as well as acceptance of new crops (largely potatoes and maize from the Americas, introduced by Europeans) and more intensive exploitation of available land.

However, other regions of the world experienced completely different demographic dynamics in this period. Australia and New Zealand, whose Aboriginal population numbered several hundred thousand, were explored by the Europeans in the mid-seventeenth century. Yet unpromising descriptions of these lands that European explorers sent back home meant that these lands remained untouched by Europeans for over

a century. Only in the late eighteenth century did European states, primarily Britain, colonize them. What makes this pattern of immigration unique is the fact that the British government decided to use Australia as the penal colony where it transported its convicts. Men outnumbered women by a ratio of 6 to 1 in urban settlements, but the countryside saw this ratio go as high as 20 to 1. The arrival of Europeans had a profound impact on the fragile ecology in Australia and New Zealand, while European diseases killed off thousands of the indigenous population.

A similar demographic catastrophe occurred in the Western Hemisphere. The population of the Americas prior to 1492 remains a hotly disputed topic, with estimates ranging from fewer than 30 million to as high as some 100 million men by the late fifteenth century. Following the European discovery of the Americas, however, the Native American population experienced a catastrophic decline, and at its lowest point after the

Thus, the population of central Mexico is estimated to have declined from over 25 million in the early sixteenth century to about 1 million a century later.

coming of Europeans it may have dropped to fewer than 5 million. Thus, the population of central Mexico is estimated to have declined from over 25 million in the early sixteenth century to about 1 million a century later. The main causes of death in this demographic catastrophe were diseases

such as smallpox, measles, chicken pox, bubonic plague, and influenza. Similarly, sub-Saharan Africa suffered a long drain on its population as a result of the slave trade that began in earnest in the sixteenth century. In the Americas, Europeans introduced plantations that created an immense demand for labor. To satisfy this demand, Portugal brought the first slaves to Brazil, and by the early 1600s some 4,000 slaves were imported annually. The slave trade increased in volume in the seventeenth century when tens of thousands of Africans were transported into the Americas and the West Indies, where they completely transformed local demographics. In his landmark study *The Atlantic Slave Trade: A Census*, Philip Curtin concluded that between 1492 and 1770 “more Africans than Europeans arrived in the Americas,” and he estimated that over 9.5 million slaves were transported to the Americas. North America was only a marginal recipient of slaves, as a majority of them were moved to the Caribbean basin and Brazil. Thus, by the end of the eighteenth century Brazil had about 2 million blacks in a population of 3.25 million people, while the census of 1790 in the newly established United States of America showed that blacks represented almost 20 percent of its population of 3.9 million people. Other scholars, like Paul Lovejoy, found that of the 5.5 million slaves transported between 1701 and 1800, the largest sources were west-central Africa (approximately 2 million), the Bight of Biafra (over 800,000), and the Senegambia (over 200,000).

Between the fifteenth and eighteenth centuries the vast majority of humanity consisted of peasantry, with up to 90 percent of people living off the land. Only a small fraction of people lived in urban settings, but urbanization varied depending on a region. India was probably more urbanized than Europe in the seventeenth century, and probably some 15 percent of its population (approximately 16 million–17 million people) lived in urban settlements, which included such great cities

as Agra, Delhi, and Lahore (in northern India) that had populations of over 500,000 people. China also featured some of the largest cities in the world, and its capital, Beijing, probably was the world's largest city until the late eighteenth century, although its preeminence had been challenged by Agra, Constantinople, and Delphi in the seventeenth century. Europe lagged behind in terms of urbanization, and between 5 percent and 10 percent of its population lived in urban settlements by the sixteenth century. By 1500 over 150 European urban settlements were inhabited by 10,000 or more people, but only 4 contained over 100,000, and most of them were in Italy. In Russia, on the other hand, an urban network was still in its infancy, and even the capital, Moscow, had a population of only 35,000 to 36,000 in 1500. Despite political setbacks and population fluctuation, urbanization accelerated in Europe over the next 250 years. While the distribution of towns in Europe remained largely unchanged, a few new cities appeared as well. Thus, Madrid rose to prominence after 1561, and St. Petersburg was established in 1703. Antwerp, Rome, and Paris doubled in population by the late seventeenth century. London experienced an extraordinary population growth, from some 200,000 in 1600 to 400,000 in 1650 and 675,000 in 1750, becoming the largest city in Europe. As historian E. A. Wrigley estimated, about 8,000 people a year were migrating to London by the end of the seventeenth century. Considering that the entire population of England at this time was only 5 million and was growing at about 16,000 each year, London was drawing half of England's population growth into itself. In Iran, Shah Abbas made Isfahan his capital in 1598 and turned it into one of the most beautiful cities of its time. Containing perhaps as many as half a million people, the city featured one of the largest public squares in the world, which was lined by two tiers of shops, a royal palace, and mosques. Constantinople, the capital of the Ottoman empire, rapidly grew in size. By 1600 it had an estimated population of 700,000 living in the vast conurbation. Historian Fernand Braudel describes Constantinople as the prototype of the great modern European capitals that arose a century later.

The distribution of major climatic zones determined types of human habitation. A major belt of waterless land runs from the Sahara and Arabia to Mongolia. This environment was conducive to pastoral lifestyle, as people drove their herds over vast pastures. To the north of this belt extends the zone of forests that, if cleared, makes good farming ground, but most of northern Eurasia is covered by taiga, a zone of cold-weather coniferous woods, and is unsuitable for agriculture. To the south of the dry belt lies moist tropical and subtropical regions. Agriculture, with its dependence on irrigation, was possible only near permanent water sources. Thus, in northern Africa cultivation was present mainly along river valleys, the most famous of them being that of the Nile. The Iranian plateau, mostly covered by steppe and desert, restricted cultivation, while tropical and subtropical regions of Central America, northern India, Southeast Asia, southern China, and western Africa saw intensive agricultural practices. The horticulturalist communities flourished in the Amazon basin as well as along the Mississippi River. Everywhere in this world populations existed in

interconnections, as trade networks connected China to Europe and India to eastern Africa. Although initially isolated from the world, the Americas had vibrant regional trade and commerce prior to European discovery and later became a part of a global commercial exchange.

Most people farmed using methods in use for thousands of years, relying on mostly human and animal labor and simple tools to produce enough food for their own subsistence and to pay taxes. The “agricultural revolution,” which jump-started the Industrial Revolution, was just beginning at the end of the period under discussion here. The most important change in food production and consumption during this period was the result of the Columbian Exchange in which plants indigenous to the Americas were introduced to the rest of the world, while plants and animals from the Old World were transported to the Americas. The introduction of crops such as maize, potatoes, tomatoes, and peanuts made a profound impact on the quality of life, as it resulted in huge increases in food production, improvement in dietary consumption, and subsequent population increases.

Human lives were subject to the rhythm and quality of harvests, which in turn depended on climatic rhythms of the planet. In the medieval period a warmer climate, known as the Medieval Warm period, allowed humans to migrate to northern territories and produce bountiful crops, which led to increased population. However, this warm period was followed by a global cooling down in the Northern Hemisphere.

The Little Ice Age had a profound influence on humankind, although its effects were not uniform throughout the world. Thus, Viking colonization of Greenland was interrupted, and the existing colonies soon disappeared.

During the ensuing period, known as the Little Ice Age, winters became colder and more severe, while fluctuations in drought and rainy periods intensified. Scientists disagree about the precise dates when it began, but cooler temperatures prevailed between the fourteenth and eighteenth centuries, peaking in the late seventeenth century. The Little Ice Age had a profound influence on humankind, although its effects were not uniform throughout the

world. Thus, Viking colonization of Greenland was interrupted, and the existing colonies soon disappeared. In China, colder winters in Jiang-Xi province destroyed the orange orchards that had thrived there for centuries. We know less about the effect of global cooling on people in North America because of the lack of written records. Native American communities certainly would have experienced major hardships, as attested by experiences of European settlers on the East Coast of North America who suffered from severe drought, malnutrition, and lack of good drinking water between 1560 and 1612. Scholars also suggest that the Hohokam civilization, which flourished in Arizona, may have disappeared as a result of climate change in the fourteenth and fifteenth centuries.

In Europe, this cooling meant that snow and ice remained in fields until late in the year, and grains and vegetables no longer had time to ripen. The decline in agricultural output oftentimes meant starvation and disease, which in turn affected political structures and produced conflicts. In the 1690s western Europe experienced the coldest decades

in 700 years, which resulted in widespread famine, misery, and unrest as peasant uprisings shook some of France's provinces. The Little Ice Age also had a profound effect on the economic and demographic situation in Europe. During the winter months major rivers froze over for prolonged periods, seriously hampering trade and commerce. Smaller harvests produced lower employment and higher prices for food, thus reducing the overall standard of living. As the amount of harvest declined, the size of families shrunk as well. Poor nutrition meant that fewer children survived infancy, and adults became more prone to diseases.

Around 1450 the world included a vast array of political entities that contained most of human population. Most of these polities were small kingdoms, principalities, or city-states that were crowded throughout Central America, sub-Saharan Africa, Southeast Asia, and Europe. But beside them existed vast empires embracing millions of people, such as the Ottoman empire, Ming China, Mughal India, Safavid Persia, and Inca Peru. Human societies were divided into social classes and hierarchies characterized by unequal access to power, privilege, and other resources. These divisions often were shaped via elaborate ideological systems based on shared religious beliefs. The medieval concept of dividing human society into three orders of "those who pray, fight, and work" (clergy, nobility, and the rest, respectively) experienced a major transformation. Although the formation of social groups and classes bore peculiar marks of indigenous customs and traditions, some general observations can still be made. Whether in Europe, the Middle East, or China, at the top of the social pyramid were emperors, kings, and sovereigns of various kinds. Their families, augmented by larger aristocracy, comprised a social group by themselves, and their internal struggles were frequently the source of much political (and social) conflict. Beneath them we can identify several groups that were common to most societies: religious officials and authorities, state officials and administrators, merchants and traders, artisans, craftsmen and servants, peasants and farmers, and slaves and serfs. Naturally these were not rigid categories, and some often overlapped or blended together or were missing completely. Thus, in Europe successful merchants often bought titles and meshed with aristocracy; in the Ottoman empire and Mughal India, state officials could also be religious leaders; and in Ming China, landowning aristocrats were largely absent.

—Alexander Mikaberidze

■ Introduction: The Little Ice Age and Climate Change

Humanity has been at the mercy of the environment during its entire existence. Only recently have humans been able to shape some elements of the environment to their will, and yet despite mankind's modern techno-

logical advances, climate change continues to threaten. One can imagine how helpless humans felt in confronting nature centuries ago. For thousands of years human lives were subject to the rhythm and quality of harvests, which in turn

► RE-CREATING PAST CLIMATES

How do historians, archaeologists, and climatologists re-create temperatures and other climatic conditions during historical periods when no accurate records were kept? Scholars use a variety of methods to re-create past climates. The size of tree rings is dependent on climate, and dendrochronologists collect samples from around the world to compare them. Palynology deals with plant pollen that can survive for prolonged periods in very harsh conditions. Palynologists find plant pollen during archaeological excavations or purposeful studies in deep peat bogs and can determine which plants grew in a given area at a particular time. Since plants tend to flourish in a specific environment, this information allows scientists to make assumptions about climate as well. A closely related field of science, paleoethnobotany explores how plants were used in the past

and provides additional clues about climatic conditions. Scientists examine seabed deposits to measure the amount of oxygen contained in shells and skeletal remains, which varies depending on temperature conditions at the time. They also utilize the so-called obsidian hydration method to establish actual temperatures in the past. Obsidian is a type of volcanic glass whose surface absorbs water at various rates depending on temperature. Scholars investigate obsidian's outer layer, called the hydration layer, to measure its thickness and determine temperature conditions at the time the layer formed. Both in the Arctic and the Antarctic, scientists drill ice cores from glaciers that trap water, impurities, and air bubbles from hundreds of thousands of years ago and can provide a narrative of changing conditions over long periods of time.

—*Alexander Mikaberidze*

depended on climatic changes. Between roughly 900 and 1200 some parts of the world experienced what scholars often refer to as the Medieval War period, when warm climate produced favorable conditions for the growth of human societies. But such warm periods were usually punctuated by colder eras. Periodically climatic fluctuations caused enormous ice sheets to spread across the globe, bringing with them a cold climate. These glaciers have advanced and retreated several times in Earth's existence, although their precise number and nature are being bitterly debated. Conservative estimates suggest that earth has experienced six ice ages, and one of them is associated with a period of advances of glaciers between 1400 and 1850.

The term "Little Ice Age" was coined (unintentionally) by the famous French glacial geologist Francois Matthes in 1939. Matthes used this informal term to describe glaciations of the past 4,000 years, with no intention of distinguishing specific colder eras from warmer periods. However, the term stuck around, and historians usually use it to describe the colder climate of the fourteenth through nineteenth centuries. Scholars note that starting in the late fourteenth century temperatures fell by several degrees, ushering in a gradual cooling down in the

Northern Hemisphere, with winters becoming colder and more severe. An even greater cooling occurred during the late seventeenth century and the early eighteenth century when the number of sunspots decreased during the Little Ice Age, suggesting that the sun emitted less heat than it did in warm periods; another contributing factor may have been an increase in volcanic activity that contributes to the creation of sulfate aerosol that reflects solar radiation back into space, resulting in cooler global temperatures. This activity reached its height between 1645 and 1715, the coldest period of the Little Ice Age. This meant that snow and ice remained in fields until late in the year, and grains and vegetables no longer had time to ripen. Western Europe experienced the coldest decades in some 700 years, which resulted in widespread famine, misery, and unrest. Several successive cold winters and bad harvests in the 1780s directly contributed to the start of the French Revolution, which profoundly transformed Europe.

The concept of the Little Ice Age, however, has recently evolved from an idea of a continuous centuries-long period of lower temperatures to a more complex view of temporal climate variability. There were distinct periods of cold climate that occurred in many parts of the

globe, but they did not necessarily occur synchronously and were not widespread. For example, while glaciers advanced in the Alps in the 1650s and continental Europe suffered from cold temperatures, Iceland enjoyed a relatively mild period with infrequent sea ice. In Africa, the Sahel (territory just south of the Sahara desert) and the south African region experienced increased dryness, while the water level in Lake Malawi (between Tanzania, Malawi, and Mozambique) decreased between 1500 and 1850. At the same time, data also indicates that rainfall increased in eastern Africa as the water level in Lake Chad (Chad) and Lake Naivasha (Kenya) rose, and the Nile River flows were high. In North America, colder weather compelled the Inuit to abandon their whaling and hunting sites and migrate to southern regions.

Food Production and Population Change in Central Africa

The reconstruction of central African population dynamics from 1450 to 1770 represents a significant challenge. There is little consensus on the region's population totals or distribution in 1450. Further, any attempt to reconstruct the population over the course of the period is complicated by two factors: the population loss and displacement fomented by the transatlantic slave trade, which hit the region of central Africa particularly hard, and the introduction of New World crops, which substantially enhanced the ability of the region's inhabitants to produce food.

In the mid-fifteenth century, the region of central Africa was likely very sparsely populated, with the total population for the region comprising only a few million people. Much of this region was covered by dense forest and rain forest, making extensive human habitation difficult. Agricultural populations did exist in the region, growing oil palm, yams, bananas, and plantains, but their settlements were generally small. Much smaller concentrations of foragers were also spread across the region, with the two groups often interacting through trade and marriage. A notable exception to this demographic distribution, however, was the kingdom of KiKongo, which had developed near the mouth

of the Congo River in the latter fourteenth and early fifteenth centuries. KiKongo is an example of how African populations during this period were increasingly carving out space for extensive population growth even in the continent's forest and rain forest regions. By 1450 KiKongo's capital of Luanda was among the first urban outposts in this challenging environment, with a population likely totaling several thousand.

The advent of Portuguese contact in the latter fifteenth century integrated KiKongo into the developing Atlantic economy and resulted in two contradictory demographic forces into the region: the demand for slave labor and the introduction of new crops. The Portuguese brought a demand for slaves, a demand that would grow significantly over the course of the next two centuries. It is estimated that central Africa would provide nearly a third of the total population exported to the Americas during this period, with as many as 4 million people being transported to the Americas from the region between 1500 and 1850. Notably, such figures do not include those who were killed in the violence engendered by the slave trade, numbers that may well total another 4 million. Given the low population of the region in 1450, the impact of such population losses over the next 300 years may well have led to shrinking, rather than growing, populations in the region.

Some scholars have argued that the loss of population to the slave trade may have been offset to some degree by the introduction of new food crops from the Americas. Corn (also known as maize) and cassava (also known as manioc) were the two most significant crops introduced into the region. Both significantly added to the region's potential to produce food. Because corn grows so quickly, it allowed local populations to get in two crops per season, whereas grains such as millet and sorghum could only produce one. Cassava was also significant in that it was a forest crop that could be grown without the necessity of clearing large tracks of land. Cassava is also drought resistant and can be left in the ground until needed, protecting it from pests such as locusts. Both crops were quickly adapted by central African populations and had become dietary staples in the region by the early 1700s.

The interplay of the populations lost to the Atlantic slave trade by central Africa and the increased potential for population growth facilitated by the introduction of New World crops into the region highlight the complexity of forces that acted upon central Africa during this period in world history.

Climate Changes in Early Modern Southeast Asia

In the seventeenth century, a group of interrelated factors—demographic, agricultural, political, economic, and climatic—resulted in a general global crisis. Parts of the Northern Hemisphere underwent a significant warming period during the late Middle Ages that then led to a period of cooling during the early modern era in what scholars called the Little Ice Age. Prior to the last 30 years, debates about the Little Ice Age (which lasted from approximately the sixteenth century to the mid-nineteenth century) centered on Europe. Although scholars do not agree on the exact time period, current research indicates that climate change significantly impacted parts of the Southern Hemisphere as well, including Southeast Asia.

Climate change can broadly impact people's ability to produce crops and maintain healthy communities. The cooling period that led to the Little Ice Age resulted in a reduction of rainfall. This critical change in climate was disastrous for human communities, contributing to high food prices, disease, and high mortality. Unfavorable weather conditions also led to health epidemics, famine, harvest failures, and economic depression for people living in the region.

The climate in Southeast Asia was impacted by a variety of climate change patterns including volcanic activity, solar activity, increased ENSO

(El Niño–Southern Oscillation) cycles, and decreased monsoon rainfall. Researchers have recently uncovered evidence that the droughts in Java during the seventeenth century and El Niño activity were connected. Volcanic activity also impacted the climate as volcanic ash exploded into the atmosphere, covering the earth and blocking normal solar radiation, which led to a cooling of the earth's temperature. Unlike the amount of climate data available for Europe, data from Southeast Asia is sparse with less written documentation available. Therefore, our current understanding of the climate during the early modern period comes from piecing together evidence from various data sources.

Communities in India, Indonesia, and the Philippines depended on the cycle of wet and dry monsoons. Overflowing rivers provided resources for rice planting. A disruption in the growing season, such as the rice shortages in various parts of Indonesia (Makassar in 1624, Bali in 1633, and throughout other cities from 1673 to 1676), took a terrible toll on humans living in the area. Detailed records and tree-ring data show that the Chinese population dropped 40 percent between 1585 and 1645 due to severe drought conditions that caused the starvation of thousands and sparked a rebellion that marked the end of the Ming dynasty.

Indian records from the seventeenth century indicate that infrequent monsoons seriously depleted water supplies. Areas of India, Siam, Burma, and Thailand suffered harvest failures and famine in the late 1630s and 1640s due to drought. Analysis of tree-ring samples from Java's teak forests provides rainfall data for the period 1514–1929. The years from 1598 to 1679 showed the lowest levels of rainfall. As a result, several regions experienced drought during specific periods: 1605–1616, 1633–1638, and 1643–1671, the most critical period with the least amount of rainfall.

Climate changes also contributed to increased disease in areas. Drought leads to crop failure, malnourishment, and a lack of clean water. Between 1613 and 1659, several regions experienced epidemics that significantly reduced the population, including Maluku (1613) and Java (1625–1626) in Indonesia, Kedah in Malaysia (1614), and Siam in Thailand (1659). Smallpox

► HISTORICAL MOVEMENTS OF THE HIMALAYAN GLACIERS

The Himalayan mountain range in the Indian subcontinent is home to nine of the highest mountain peaks in the world, including Mount Everest. Today the Himalayas contain the largest area of glaciers outside of the polar caps. These particular glaciers are important to the earth's ecosystem because they contain 70 percent of the world's freshwater supply.

Glaciers go through periods of expansion and retreat, impacting the climate and subsequently human communities. Glaciers worldwide are currently retreating; those in the Himalayas are diminishing at an alarming rate. Although prior evidence had yielded various interpretations, current research indicates that most of

the Himalayan glaciers began to retreat in the mid-eighteenth century at the end of the Little Ice Age.

The lack of historical records prior to 1850 CE in the Himalayan region means that scientists had to identify other data to measure glacial change. Researchers gathered data by analyzing the growth rate of lichens (composite organisms) and dating moraines (unconsolidated glacial debris) with tree-ring records. These records indicate that the largest lichens date from between 250 and 315 years ago, therefore placing the maximum expansion and subsequent retreat of the glaciers within this period.

—Kim Kennedy White

was the most common epidemic during this time. The tree-ring samples from Java showed that 1664 and 1665 were the driest years in a 400-year period. During those same years, most of Indonesia was greatly impacted by the worst epidemic of the early modern period.

The available data show correlations between drought and population decline, as evidenced by records from the Philippines and Indonesia indicating significant decreases in population during the driest periods and increases in population during the more favorable climate conditions of the 1680s and 1690s. The impact of the Little Ice Age and climate change in Southeast Asia in the centuries preceding and following the early modern period is not well understood. Scholars continue to uncover and interpret climate change data for Southeast Asia not only to understand the impact of climate during the early modern period but also to understand the long-term and complex effects of climate change in today's world.

Cold Times—The Little Ice Age in Western Europe

From the early fourteenth century until the mid-nineteenth century, the Northern Hemisphere endured an extremely harsh climatic pattern known as the Little Ice Age. The harsh weather patterns—peaking in the mid-seventeenth and early eighteenth centuries—triggered massive social, political, and economic changes in its wake. The influence of climate on agriculture, disease, and political structures, already vulnerable due to endemic warfare and instability, was considerable. In the context of the resulting food shortages, famines, and rebellions, the Little Ice Age explains much of the social unrest and economic dislocations that characterized this period in European history.

CLIMATE AND THE PLAGUE

While there is a direct correlation between climate changes and the prevalence of disease in the wake of the Little Ice Age (1650–1700), it is only among diseases caused by malnutrition such as diarrhea and diphtheria, among others. The recurrence of the bubonic plague in Europe, making its presence known from time to time, was notably absent during the duration of the Little Ice Age. The bubonic plague existed in fleas that traveled throughout Europe on rats, which usually found ample transportation throughout Mediterranean trade routes to the Levant. In order for such fleas to reproduce in adequate numbers for spreading the bubonic plague, it was necessary for them to have sustainable environments to reproduce. The climatic fluctuations that Europe experienced during this period seriously hampered the ability of the flea eggs to develop, much less hatch. The resulting decline of the plague in some areas was a result of this phenomenon. However, after the ebb of the Little Ice Age and the stabilization of climate patterns, the debilitated state of many Europeans due to the poor harvests of the previous period made them susceptible to the increasing resurgence of the surviving flea populations. The result was an increased number of deaths now attributable to the plague in addition to diseases of malnutrition.

—*Abraham O. Mendoza*

The severe climatic conditions that characterized the Little Ice Age in Europe have been attributed to a host of reasons. The lack of sunspots, solar flare fluctuations in the sun that affect conditions on earth, is a probable cause. The reason for this dearth in sunspots is attributed to a series of major volcanic eruptions from 1638 to 1643 that unleashed a large amount of dust into the atmosphere that reduced the amount of solar energy capable of reaching the earth. Agricultural and church tithe records showed that during these years harvests decreased dramatically. During the winter months major rivers, such as the Thames in England, froze over for long periods, seriously hampering trade networks and commerce. The advance of glaciers in some Alpine regions claimed former arable farmland in addition to villages. This seriously affected the

livelihood, not to mention the survival, of local communities solely dependent on such harvests for their day-to-day existence.

The harshest weather of the Little Ice Age was during the late seventeenth and early eighteenth centuries, reversing existing demographic trends. From about 1000 to 1300, the population of western Europe is estimated to have nearly doubled, from about 40 million people to about 75 million. The economy expanded considerably as well, resulting in the improvement of the standard of living for many Europeans. People customarily married young and began reproducing immediately. The Little Ice Age reversed these trends. The smaller harvests following the climate change led to a drop in population as starvation elevated the already high infant mortality rates. This in turn led people to marry later. Since women were relegated to having children after marriage and before menopause, this resulted in smaller families. Extensive periods of hunger weakened the population, making it vulnerable to disease. Epidemics, such as the plague, typhus, dysentery, and typhoid, took a great many lives as a result. The reduction of harvests resulted in less need for labor and in higher prices for staple foods. The impact on the economy due to increased prices and lower employment resulted in more starvation and a lower standard of living for a large number of people.

The Little Ice Age contributed to the discontent that the economically displaced displayed toward the governing authorities but also mirrored other social and political strife occurring simultaneously. The relationship between the social and economic consequences of the Little Ice Age contributed to greater instability, which resulted in upsetting the political structures of the time through a series of multiple rebellions throughout Europe. The combination of war, disease, and famine devastated the population of Europe and increasingly resulted in immense political change. The existing unrest that already existed due to the Protestant Reformation and the centralizing tendencies of absolutist monarchs further exacerbated the tenuous situation. Among the large-scale conflagrations of this period are the English Civil War (1642–1651), the Thirty Years' War in the Holy Roman Empire (1618–1648), and the Catalan revolt in Spain

(1640–1653). The commercialization of England during this period is attributable to this disruptive climatic change. The decline of harvests in Britain and the onset of civil war, while destructive to society and the economy, were offset by the economic linkages created by Oliver Cromwell due to his wars with the Dutch to assert English naval supremacy (1653–1654). The end result was the wane of Dutch economic power relative to the emergence of England as a major player in European and Atlantic trade. Within Britain, the economic dislocations caused by poor harvests were more than made up by England's newfound role as a major global commercial power.

Creeping Cold—From New England to Coastal Alaska

Diaries, letters, and other historical documents reveal that people all over the world experienced the effects of a deepening cold period known as the Little Ice Age beginning about 1250 CE. Scientists disagree about the precise dates that it began, but the world endured about 500 years of colder weather after this time. Earth's climate has gone through numerous cycles of global warming and cooling in the 10,000 years since the end of the last major ice age. Although far smaller than the temperature swings of the Pleistocene during which vast ice sheets expanded over large parts of continents and melted away several times, these oscillations nonetheless have left their marks on human cultures and natural ecosystems. The global cooling event affected different areas at different times, but in

general temperatures were one to two degrees cooler than they are today. Glaciers worldwide advanced considerably during the Little Ice Age.

During a warmer period prior to the Little Ice Age known as the Medieval Warm period, people migrated northward, establishing farms and growing crops even in subarctic areas. However, when the colder temperatures arrived, crop failures led to famine, diseases, and death. With each climate change, whether global or local, communities of plants and animals shifted north or south or were disrupted, leading to the creation of new groupings of species. Likewise, human cultures were uprooted and driven to more favorable locales, or people adapted by changing their technologies and behaviors.

Unlike many earlier climate swings, the Little Ice Age was abundantly documented by human observers throughout the literate world. Galileo invented the thermometer in the midst of the Little Ice Age, and in central England reliable monthly temperature records begin in 1659. Where written records are unavailable, more information about climate can be determined by geologists and botanists. Scientists have several methods for measuring climates of the past. "Dendrochronology" is the term used for examining tree rings, which are formed by the annual growth of wood in the trunk. During warm and moist years trees grow fast, adding thick rings; during cool or dry years, rings are thin. These patterns of thick and thin rings help researchers reconstruct changes in environment during the tree's lifetime.

A second very important scientific method uses cores of ice obtained by drilling into glacial ice at the North and South Poles and on high mountains to obtain records of snowfall, dust, and atmospheric chemicals contained in the ice. These cores provide information on temperature, precipitation, and even global wind patterns if the source of the dust can be determined. Paleobotanists examine layers of cores similarly drilled in lake sediments to analyze plant pollens and reconstruct the types of vegetation growing in the area. Vegetation responds quickly to temperature and rainfall changes.

The effects of the Little Ice Age were anything but uniform throughout the world. Cold and erratic weather patterns produced numerous crop failures in northerly areas such as Scotland and

➤ COLD, CORN, AND CULTURE IN THE PREHISTORIC NORTHEAST

Maize, or Indian corn, first arrived in northeastern North America during the Medieval Warm period before the Little Ice Age. Archaeologists have dated maize in Ontario at 600 CE and in New York at 1000 CE, but larger caches of corn did not appear until 1,200 or 1,300 years ago. Central Americans developed corn agriculture for warmer climates more than 3,000 years ago, but it was not until the improvement of a type called Northern Flint that farmers could grow corn in more temperate climates. Even with this biological advance, corn still required 120 days of warmth in order to ripen.

Although American Indians practiced maize horticulture by 1000 CE, many tribes of the Northeast could not rely on it as their primary source of food. New England's Algonquian peoples, particularly, experienced difficulty in growing maize because of poor rocky soils and the cool rainy weather of the Little Ice Age, although in areas such as the Connecticut River valley large fields of corn could have been grown and supported larger villages. Early European visitors noted that these tribes left their maize under the care of the elderly and children while adults pursued other subsistence activities, and archaeological sites indicate a high degree of seasonal mobility. Europeans describe finding maize often stored in subterranean pits but in such small quantities that it would have served as a dietary supplement rather than the major staple food. When American Indians did eat corn, they mixed it with beans and called the dish *sagamite* (or succotash).

Hunting and gathering of a variety of plants and animals formed the core of the diet of aboriginal peoples in prehistoric New England. While we know that maize horticulture was practiced by the New England Indians from Maine (but only along the Saco and Kennebec rivers) to Connecticut, it may not have consumed much of their time or energy. After the planting of corn, Native American peoples would disperse for two to three months as the corn ripened to hunt and gather elsewhere. Thus, the Algonquians of the region may be seen as mobile farmers or as foraging horticulturalists. In 1634 the English observer William Wood reported that the people of Massachusetts Bay

Members of the Hopewell culture gather crops of maize and squash. The Hopewell were the first Native American people fully committed to agriculture. (North Wind Picture Archives)

relied on waterfowl, game and fish, roots, beans, and clams in winter and on shellfish and berries in summer, suggesting a very diverse diet.

Just 50 years later another witness, John Josselyn, noted that the people of the Maine coast relied upon fish, fowl, wild game, dried oysters, lobsters, eels, eggs, Indian corn, kidney beans, ground nuts, chestnuts, roots, and berries. For the Hudson Valley, another visitor agreed that Native American people supported themselves with hunting, fishing, maize, and beans. No doubt cold, wet weather, and poor soils prevented the development of large-scale agriculture and large communities in prehistoric New England, so New England peoples adapted to the numerous natural resources in their environment that actually provided a nutritious and varied diet.

—Pauleena MacDougall

Norway. Perhaps hardest hit were the Norse settlements in Iceland and Greenland. The population of famine-ridden Iceland dwindled during the Little Ice Age to half its previous number. Greenlanders fared even worse. Growing sea ice cut off communication with the outside world beginning about 1370, and when German ships landed in Greenland more than a century later, they found a single frozen corpse but no living colonists among the ruins. In 1645 glaciers in the Alps and Scandinavia grew farther down mountain slopes and valleys than they had in thousands of years. Sea ice choked much of the North Atlantic, causing havoc with fisheries in Iceland and Scandinavia. Eskimos paddled their kayaks as far south as Scotland. At the same time in China, severe winters in Jiang-Xi province killed the last of the orange groves that had thrived there for centuries.

In addition to a general cooling trend, greater fluctuations in climate alternating in drought and rainy periods occurred during the Little Ice Age. The extremes of rainfall and cold placed even greater stress on agriculture, health, and economics. The growing season changed by 15 to 20 percent between the warmest and coldest times of the millennium. That is enough to affect almost any type of food production, especially crops highly adapted to use the full-season warm climatic periods.

Cod fishing greatly decreased at the Faeroe Islands, but conversely the fertile fishing grounds of the present-day Newfoundland Banks were thought to have been found by fishermen in the late 1400s who were looking for the fish stocks that had deserted their former grounds as the result of the movement of colder waters from the north.

Storms that caused more than 100,000 deaths were also reported in 1421, 1446, and 1570. Additionally, large hailstorms that wiped out farmland and killed great numbers of livestock occurred over much of Europe due to the very cold air aloft during the warmer months. Due to severe coastline erosion and high winds, great sandstorms developed that destroyed farmlands and reshaped coastal land regions.

Many glaciers in Alaska, Canada, and the northwestern United States grew larger during the Little Ice Age. European explorers first sailing along the Alaska coastline in the 1790s noted

only a small embayment along the coastline. By the 1880s the glacier that filled what became known as Glacier Bay had retreated, leaving a bay that extended nearly 40 miles (64 kilometers). The glacier continues to retreat, and today Glacier Bay extends more than 60 miles (96 kilometers) into the Alaskan coastline.

In North America some hunter-gatherer communities may not have suffered as much as the new agricultural communities, but that does not mean there was no hardship. We know less about the effect of climate on population in North America than in Europe and Asia because written records do not exist. Smaller, more mobile Native American communities could easily adapt to changing climate. Few really large population centers developed during this period, with some notable exceptions. Cahokia, a large urban cluster of about 30,000 people, occupied a 6-mile (10-kilometer) stretch along the Mississippi River in present-day Louisiana. The Mississippian society grew fields of corn, beans, and pumpkins and built large earthworks upon which lived the city's chiefs and priests. The society had developed a new variety of maize called Northern Flint that matured in a shorter time and could be cultivated in temperate northern latitudes. Did the creeping cold lead to their demise in the 1300s? Scientists are uncertain. Certainly the alternating drought and rainy seasons had some effect. In the southwest, Anasazi communities such as the Chaco Valley system collapsed due to drought after about 1130. Likewise, the Hohokam civilization that relied on irrigated crops and flourished in what is now present-day Arizona collapsed in the fourteenth and fifteenth centuries, and its villages were abandoned. Increasing drought, floods, or salination may have caused crop failures.

The Little Ice Age also created difficult conditions for European settlers in North America. Severe drought occurred between 1560 and 1612 as English colonizers were settling along the Carolina and Virginia coasts. Roanoke Island, North Carolina, experienced two years of drought between 1587 and 1589. Jamestown also experienced severe drought in 1607, leading to crop failure and starvation. Only 38 people survived out of the original 104. Eighty percent of the 6,000 settlers who arrived between 1607

and 1625 perished from malnutrition and shortage of good drinking water.

Scientists have identified several possible causes of the Little Ice Age from outside the oceanic, atmospheric, and land systems: decreased solar activity, increased volcanic activity, and ocean currents. Some have also speculated that depopulation of Europe during the famine and plague and the resulting decrease in agricultural output may have prolonged the Little Ice Age. Other researchers have examined earthly causes. Volcanic eruptions are known to meddle with climate by injecting a veil of sun-blocking dust into the atmosphere. There were eruptions that are more frequent during the Little Ice Age than during the twentieth century. These eruptions are short-term events that may have exaggerated the effect of the Little Ice Age but probably were not a cause. Most prominent was the 1815 eruption of Tambora in Indonesia. It pumped into the atmosphere vast amounts of ash. The following year has been called the Year without a Summer. In June and July 1816, New England and northern Europe suffered frost and even snow.

One potential source of climate change also may be the North Atlantic currents. Warm water in the Gulf Stream moves north along the surface, cooling as it travels. By the time the surface water reaches the far northern portions of the North Atlantic basin, it has cooled and grown denser than the underlying layers of ocean and begins to sink. The water then travels south along the bottom, driving an aquatic conveyor belt that spans the globe. But researchers suspect that if enough fresh water, perhaps from melting ice, is injected into key spots in the North Atlantic, it can virtually shut down the

conveyor. Fresh water is more buoyant than salt water and can form a layer that blocks the circulation. The North Atlantic region would then cool. If the fresh water is reduced, researchers say, the reverse can happen, warming the North Atlantic region.

■ Introduction: Natural Disasters and Population

Natural disasters, such as earthquakes, volcanic eruptions, and extremes of weather, have been the costliest events throughout history. The least predictable of disasters, they often produce human tragedies on

a vast scale. The early modern world experienced several such natural disasters that had profound effects on human demography as well as contemporary politics and culture. In 1556 one of the deadliest earthquakes in history

struck the northern Shaanxi region of China. The earthquake completely devastated some 11 provinces. Entire mountains and rivers changed as the earthquakes pushed the earth's surface dozens of feet up or down. Houses, temples, and fortifications were completely demolished, and the loss of life is estimated to have exceeded 800,000 people. Aftershocks continued to shake the region for weeks afterward. This devastating earthquake, although unique in its strength, was not an isolated incident. The northern Chinese provinces experienced earth trembles in 1303 and 1695, while powerful earthquakes struck the provinces of Fujian, Gansu, Taucheng, Hebei, and Yinchuan between 1604 and 1739.

Less than 40 years after the Shaanxi earthquake, on February 19, 1600, South America witnessed one of the biggest volcanic eruptions in all of recorded human history when the Huaynaputina Mountain close to Arequipa (southern Peru) erupted. Ranked sixth on the Volcanic Exclusivity Index, the explosion was as powerful as the famous Krakatau eruption in 1883. The Huaynaputina eruption sent thousands of tons of ash, smoke, and fragments of volcanic rock with terrific force high into the atmosphere. Most of the nearby area suffered complete devastation, while ash fall was reported hundreds of miles away in what is now northern Chile and western Bolivia. Lima, the capital and largest city of Peru, lay under a thick layer of ash that ruined regional agriculture, which took decades to fully recover. In the Pacific, offshore from Peru, British sailors, upon hearing explosions, thought they were about to be attacked by enemy warships. The Huaynaputina eruption had an effect on a global scale as well. Recent studies on tree rings indicate that the next two years after the eruption were the coldest in hundreds of years in Europe. Records in Switzerland, Estonia, Latvia, and Sweden show that the winters of 1601-1603 were among the coldest years, freezing rivers and harbors where crucial trade was conducted and causing record floods in the spring. In Russia this climate change resulted in the worst famine that realm had experienced in centuries, and tens of thousands of people died. Government's failure to alleviate the calamity produced a political turmoil that eventually led to the overthrow of Tsar Boris Godunov, a turning point in Russian

history. Elsewhere grape harvests failed or were late in France, Germany, and South America, while peach trees blossomed late in China.

In the mid-seventeenth century, London, one of the largest cities in Europe, became the scene of a different kind of disaster. The bubonic plague, which devastated most of Europe in the fourteenth century, made an unexpectedly strong comeback in England in 1665. The country had enjoyed an economic boom, and London was at the epicenter of this success. Its population rapidly increased, causing overcrowding and neglect of hygiene, which facilitated the spread of diseases. Thousands of people were horrified to see their bodies covered in black boils in the armpits, neck, and groin, the first signs of the deadly disease. Death came swiftly to these unfortunates, as the disease spread easily from person to person through the air. The first victims of the plague were diagnosed in late 1664, and by late spring the disease claimed over 7,000 lives every week. The king, his retinue, and wealthy residents fled the city, leaving behind the poor and wretched who could not afford to leave and whose malnourished bodies could hardly resist the disease. As many as 100,000 people died over the next six months. Physicians could provide no explanation for the sickness, nor could they provide any treatment. The few who braved staying in the city to care for the infected wore leather masks with glass eyes and a long beak filled with flowers and herbs that were thought to ward off the illness.

The English writer Daniel Defoe, author of the famous *Robinson Crusoe*, witnessed the devastating effect of the Black Death. He described London as an abandoned and despondent city, firmly in the grips of eerie silence that was broken by the occasional sound of the carts carrying the dead. Many buildings were quarantined, their residents forbidden from leaving the building. Every day hundreds of bodies were dumped unceremoniously in mass graves. At the time a young man was studying at Cambridge, and upon the news that the Black Death spread to this city, his mother took him home to northern England, where, in solitude and isolation, the young man concentrated on his mathematical studies. Eventually the world would know this man as Sir Isaac Newton, while his

Principia Mathematica would become one of the greatest scientific works of all time.

London had barely recovered from the Black Death when early at dawn on September 2, 1666, it suffered from another disaster. Some residents woke up that morning to find their rooms full of smoke. As they rushed outside, a shocking sight of numerous buildings consumed by flames appeared in front of them. As thousands of residents rushed to escape from the homes, fire quickly spread from one wooden structure to another. Before the end of the day the fire was out of control and burned for three days, leaving behind the desolate mass of ruined homes and stumps of chimneys. The fire consumed over 13,000 houses, 87 parish churches, St. Paul's Cathedral, and most of the municipal buildings. Social and economic consequences of this disaster were overwhelming, but London was rebuilt within years of the disaster, and its economy rebounded.

Across the Atlantic, a Caribbean port town was not as fortunate. On June 7, 1692, Port Royal (Jamaica), one of the busiest and wealthiest ports in the West Indies, experienced a powerful earthquake followed by a tsunami. Most of the town sank into the sea immediately after the main shock, while the few remaining buildings were swept by the huge oceanic waves that the tsunami brought onto the shores. By the end of the day most of Port Royal was destroyed and lay beneath the waters of present-day Kingston Harbor. About 2,000 people (out of some 6,000) died beneath the ruins or were swept into the sea, while another 2,000 to 3,000 perished from wounds, disease, or malnutrition in the days after the catastrophe. Looting and robbery spread rapidly as survivors fought over meager resources. Port Royal struggled to recover but never recovered its former glory. Devastated by fires in 1703 and 1750 and hurricanes in 1722 and 1774, Port Royal declined in importance as colonial government moved to Spanish Town, while trade shifted to Kingston. By the late eighteenth century the town was almost entirely abandoned, and today less than 2,000 people reside there.

Only eight years after the disaster at Port Royal, another catastrophic event shook the Western Hemisphere. Early on the morning of January 26, 1700, the undersea Cascadia thrust fault ruptured with an estimated magnitude of

9.2, shaking the ocean floor west of Seattle and producing a vast tsunami that swept over the coastal area and destroyed everything in its path. The Native Americans who resided in the region left no written evidence of this event, but scientists were able to reconstruct its events based on dendrochronology, soil studies, Native American oral traditions, and Japanese records that show the appearance of a tsunami in 1700. Japanese sources speak of flooded fields, shipwrecks, damaged houses, fires, and panic. But Japan was thousands of miles away from the epicenter, and one can only imagine the catastrophic effect that this event had on indigenous societies residing along the coastline. The oral tradition of the First Nations people tells of complete destruction of the houses of the Cowichan people on Vancouver Island and earth trembles so violent that people could not stand and so prolonged that it made them sick.

Arguably the most famous natural disaster of the eighteenth century took place on November 1, 1755, when a powerful earthquake struck near Lisbon, the capital of Portugal. As thousands of residents flocked to their churches, the magnitude 9 shockwave destroyed most of the city and produced a tsunami that swept ashore, killing thousands and inflicting further damage. Some 40,000 people died in the Portuguese capital, while several more thousands lost their lives in Spain and Morocco. Lisbon's magnificent Manueline architecture as represented in palaces, libraries, and churches was destroyed. People were stunned by the scale of destruction and the fact that it took place on All Saints Day, a sacred holiday in the Catholic realm. In a society that believed that everything on the earth was part of an orderly creation guided by its Creator for the benefit of humanity, some began to question how such a tragedy could occur on a holy day and why the Creator allowed the deaths of so many innocent people. The leading voices of the Enlightenment launched debates on religion, theodicy, and the nature of God. The sharp-witted French philosopher Voltaire used the earthquake to criticize the belief in "the best of all possible worlds," while Jean-Jacques Rousseau called for abandonment of urban life and the return to a more naturalistic way of life.

—Alexander Mikaberidze

Natural Disasters in Early Modern South Asia

Natural disasters are complex and difficult to define as the relationship between humans and the environment is as important as the natural event itself. The peoples of the early modern period in South Asia faced numerous challenges, as the area was particularly prone to monsoons, typhoons, coastal storm surges, tsunamis, and droughts. During this time, South Asia experienced extreme weather conditions resulting in floods and drought, devastating destruction, and significant loss of human life.

Human settlements often form around rivers for the natural benefits of water supply, food, and travel. While monsoons (heavy seasonal winds) provide ample water supplies for the growing season, they also present hazards for flooding, soil erosion, destruction of agriculture, damage to human communities, and loss of life. The Ganges River has long been a source of life to people in the region and is the subject of myth and legend. In the sixteenth century the Ganges River changed course, forming numerous islands at the mouth of the Ganges and the Gulf of Bengal. While the shift in streams proved beneficial for agricultural cultivation, the heavy rains caused floods and environmental imbalances, prompting the

people to build embankments to keep rising waters at bay.

The flooding of the Ganges River impacted military campaigns as well. The memoirs of Babur (the first Mughal emperor, r. 1526–1530) and Akbar (the third Mughal emperor, r. 1556–1603) provide modern readers with vivid descriptions of changes in the region's landscape. The unpredictable monsoon rainfall was of grave concern to Mughal emperors, as the environment proved difficult for military expeditions. Deploying troops, crossing rivers, transporting weapons and equipment, and planning attacks depended on the rise and fall of the waters. Other visitors to the region throughout the sixteenth to late eighteenth centuries describe numerous instances of flooding that wiped out entire cities, killing thousands, destroying needed food supplies, and prompting communities to invoke the gods and pray for divine intervention.

Severe weather conditions can also include typhoons, tsunamis, and coastal storm surges. A typhoon is a tropical cyclone in which a low-pressure center and thunderstorms produce torrential rain and powerful winds. In the Southern Hemisphere, these storms feed on heat released from rising moist air and can create storm surges (where storms cause large tidal waves on the coast) and cyclones, causing significant damage to humans, wildlife, and the environment.

STORM SURGES AND TSUNAMIS IN THE INDIAN OCEAN

The Indian Ocean is prone to storm surges and tsunamis. Storm surges occur when severe storms and strong winds push water toward the coast (often with large tidal waves), causing a surge of water and flooding. When the ocean floor experiences earthquakes, volcanic eruptions, landslides, or tectonic plate movements, the ocean's water is quickly displaced. This causes a series of long and extremely dangerous water waves (the tsunami wave train) to reach land. These waves can travel over 500 miles (805 kilometers) per hour and often occur with little warning.

The term "tsunami" comes from the Japanese word for "wave harbor." These catastrophic events have occurred throughout the history of South

Asia, although scientists continue to gather evidence and document major storm surges and tsunamis in the early modern period. A tsunami was said to hit Maharashtra, a state on the western coast of India, in 1524, but few details are known about the cause and impact. Another large earthquake and subsequent tsunami hit the coast of the Bengal-Burma region (present-day Bangladesh and Myanmar) on April 2, 1762, resulting in the deaths of more than 500 people and causing severe damage to the city of Chittagong and raising the Arakan coast. Much of what is known about this event is anecdotal and comes from eyewitness accounts.

—Kim Kennedy White

Most sources report that one of the worst natural disasters in history occurred in 1737, when a typhoon near Calcutta, India, at the Bay of Bengal caused 20,000 ships to sink along the Hoogly River and resulted in the deaths of 300,000 people. Evidence, however, is based on reports from the East India Company. Scientists continue to examine the event in order to determine the nature of the storm and the number of deaths, since the population of Calcutta at the time was fewer than 20,000 people.

The lack of rainfall can also become a natural disaster. South Asia experienced a series of droughts and crop failures that led to deadly droughts during the sixteenth, seventeenth, and eighteenth centuries. After three consecutive seasons of crop failure during 1630–1632, the Deccan region experienced a famine that resulted in approximately 2 million deaths.

Human response can add to the toll of natural disaster. A shortfall of crops and severe drought led to the Bengal famine of 1770, resulting in the deaths of more than 10 million people, or one-third of the population. This was the first Indian famine under British rule. The British East India Company's tax hikes coincided with this famine. Reports of distress were reportedly ignored, causing further damage to the human population in the region who were also battling smallpox and other diseases as a result of the famine.

Earthquakes in the Early Modern World

Natural disasters in the early modern period left a wake of destruction not only due to their own destructive capabilities but also due to the fact that fire, disease, and a dearth of preparation by states and polities in reacting to said occurrences extended the level of destruction and chaos. While the environmental implications of natural disasters were significant, the social, political, and economic consequences also made a considerable impact on the states and peoples of this period of world history. Cataclysms like earthquakes and the resulting floods that occurred from the tsunamis that often followed left a path of destruction that societies of this period were unable to contend with, especially in those regions that were experiencing significant urbanization.

Western Europe experienced a number of earthquakes from the fifteenth to the eighteenth centuries. In 1481 the island of Rhodes in Greece experienced an earthquake with an estimated magnitude of 7.2 and a casualty rate of 30,000. However, the majority of the damage was not caused by the initial shock but was instead caused by the ensuing tsunami and the aftershocks that lasted for ten months, into 1482. Italy saw several earthquakes in this period, but probably the biggest one was the earthquake in Sicily in 1693. The quake itself registered around 7.5 and was coupled with the eruption of Mount Etna. Forty-five cities and towns were destroyed, and the casualties numbered upwards of 60,000 people. The destruction of the cities required a major rebuilding effort, which inspired a new style of Baroque architecture called Earthquake Baroque. Portugal also had two major earthquakes, both centered in Lisbon: one in 1531 and one in 1755. The sixteenth-century earthquake gave King João III the excuse he needed to petition the church for an inquisition, as people became convinced that their tolerance of crypto-Jews had angered God. The eighteenth-century quake was devastating to the country mainly because it triggered an enormous tsunami that added to the damage and chaos already caused by the main quake.

A variety of earthquakes also struck the Americas, particularly Chile, during the early

► THE GREAT FIRE OF LONDON

In 1666 London experienced a fire that devastated the entire city. During the seventeenth century London was a hodgepodge of wooden buildings constructed in a haphazard manner, as it had grown unchecked since the medieval era. It was also severely crowded, conditions that caused John Evelyn to become alarmed at the danger posed were a fire to start. Indeed he was correct, as a fire that started on Pudding Lane on September 2 soon turned into a firestorm that raged for three more days. By the time the fire had finally run its course on September 5 most of the city and its homes were destroyed, the fire only missing the Westminster district and Whitehall Palace. Despite the severity of the fire, only eight deaths were recorded. Recent historiography has begun to challenge the official death toll, stating that it was probably higher because the deaths of the poor and the middle class were not recorded, and most of the bodies would have been incinerated by the flames.

The fire did not institute a major change in the construction of London. A special Fire Court was established to deal with disputes between landlords and tenants, and decide who should pay to rebuild, based on their ability to pay. Verdicts were usually given within one day, in an attempt to speed up the rebuilding. Plans to rebuild London on a grand Baroque scale were produced but never came to fruition, as there was a major labor shortage especially once Charles II encouraged the refugees to leave and settle outside the city in the hopes of avoiding rebellion. Finally, London was rebuilt on the ruins of the old city, the only difference being that the streets were wider, the river was not blocked by buildings, and the houses were now made of stone and brick, not wood. The fire saw the advent of fire insurance. The first fire insurance company was established in 1680, and ten years later one in ten houses carried fire insurance.

—Monique Vallance

modern period. Earthquakes hit Chile in 1575, 1604, 1730, and 1751. The worst of these was the 1751 earthquake in Concepción, which rated around 8.7 and triggered a tsunami that brought up to five waves to shore. Some residents had already evacuated prior to the main shock, as several tremors had preceded it, warning the population, already used to earthquakes, that one was about to occur. The consequences of this disaster were great: the continued aftershocks prevented the reconstruction effort and even destroyed the emergency shelters built for the homeless. Even nearby cities were affected. The city of Chillán was destroyed, and its river was redirected 15 blocks. Fourteen years later, the entire city of Concepción was relocated to Valle de La Mocha in order to protect against future quakes. Farther north in the Caribbean, Port Royal in Jamaica was also hit by a major earthquake in 1692. The results of this quake were severe, as two-thirds of the town (around 33 acres or 13 hectares) sunk below sea level. In addition, approximately 5,000 citizens were killed both in the initial quake and in the landslides and tsunamis that occurred in the days to follow. While

this casualty rate may not seem very high, it was devastating to Port Royal, as the town's population had been only 6,500.

Asia is a continent that was especially hard hit by earthquakes. The casualty rate here was higher than the rest of the world combined, mainly because of the earthquakes that occurred in the Shaanxi Province of China in 1556. It is known as the third-deadliest natural disaster in history based on the number of people who died, not on the magnitude of the earthquake (which registered over 8.0). This earthquake was so deadly because the population had built their homes in caves that consisted of loess, a soft clay that had collected over the centuries. The landslides that resulted from the earthquakes buried the caves as well as the people living inside them. It is estimated that between 820,000 and 830,000 people were killed, which made up 60 percent of the region's population. An earthquake of a similar magnitude occurred in Hoi, Japan, in 1707, making it the largest earthquake in Japanese history, although the death toll was not nearly as catastrophic. The magnitude 8.6 earthquake not only triggered one of the third-largest landslides

► LISBON EARTHQUAKE OF 1755

On November 1, 1755, at 9:20 a.m. a powerful earthquake struck Lisbon, Portugal; almost an hour later, a giant tsunami engulfed the city and its environs, followed by a conflagration that destroyed much of what remained. The catastrophe killed between 60,000 and 100,000 people. The shockwaves reached as far as Finland. Tsunamis reached the southern coasts of England and Ireland, and 10,000 people were killed in Morocco.

The royal family managed to escape harm because they were in Belém, a suburb of Lisbon. Had they been in Lisbon they would have surely died, as the Paço da Ribeira, the royal palace, was reduced to rubble. With the royal family was Sebastião de Carvalho e Melo (known today as the Marquis of Pombal), the prime minister of José I. Pombal's leadership enabled the city to rebuild and recover. When asked what should be done, Pombal is reported to have said, "Now? We bury the dead and feed the living." He sent firefighters into the city to put out the flames and had thousands of corpses buried at sea to avoid disease. Chaos was also minimized with the erection of gallows at various parts of the city, a warning to looters and would-be criminals inclined to take advantage of the confusion. Immediately following

Painting of the Lisbon earthquake of November 1, 1755.
(Jupiterimages)

the disaster, Pombal and Dom José began to hire architects to plan the rebuilding of the city. One year later the city was mostly empty of debris, and the only sign of destruction was the absence of so many important historical buildings and treasures destroyed in one of the worst earthquakes in recorded history.

—Monique Vallance

in Japanese history and tsunamis but also has been linked to the eruption of Mount Fuji. The resulting death toll reached 5,000, and 29,000 houses were destroyed. Western Asia was also no stranger to earthquakes. The 1509 earthquake in Istanbul, Turkey, had a magnitude of 7.2, had 10,000 casualties, and destroyed 109 mosques and over 1,000 houses.

Sixteenth-Century Demographic Catastrophes in Peru

The Americas in the sixteenth century were the scene of some of the most devastating population crashes in human history. The population of the Americas in 1492, before European contact, has been estimated to have ranged from 50 million to 100 million; by 1600 the survivors of the massive sixteenth-century die-off numbered only an estimated 5 million to 10 million. During the sixteenth century, about 90 percent of the native population of the Americas were the victims of warfare with the invading Spanish and Portuguese conquerors, harsh and inhumane treatment, being worked to death in savage conditions, or especially European diseases to which they lacked all natural immunity.

To these general causes for the great population crash of the sixteenth century can be added

some special factors in Peru. Peru was cursed with riches in precious metals, gold and silver. The silver was most important because in Upper Peru (today Bolivia) the Spanish found in 1545 a mountain of silver, Potosi. The Spaniards quickly opened mines in this Cerro Rico (“rich mountain”) and conscripted Quechua and Aymara natives of the former Inca empire to dig and refine the ore. A new city, Potosi, grew up near the mountain. Potosi, at an elevation of 13,000 feet (nearly 4,000 meters), became the largest city in the Americas and one of the largest cities in the sixteenth-century world, with 200,000 people.

The Indian conscripts refined the silver ore by using the patio process, in which the crushed rock containing the ore is spread out on a patio and then mixed with mercury. The Indians mixed the mercury with the crushed rock by treading it with their bare feet. Since mercury is toxic and exposure to it causes dementia and then death, the Indian mortality rate was very great. Peru was doubly cursed, because in central Peru, near Lima, the Spaniards located one of the world’s greatest deposits of mercury, at Huancavelica. There the Spaniards discovered a rock mountain “soaked in quicksilver.” The rock was mined and crushed by forced Indian laborers, using hand tools. Mining the mercury, like refining the silver ore, was highly toxic, and mortality among the Indian miners was so dangerous that every morning before the Indians went down in the mines, they attended a requiem mass for the dead.

To obtain workers for the mercury mines at Huancavelica and the silver mines at Potosi, the Spanish relied on an old system inherited from the Inca empire whereby local Indian rulers (*caciques*) were responsible for drafting from the peasantry workers for public works. This system, called the *mita*, admirably suited the mine owner’s needs. Indians were drafted from agricultural villages located hundreds of miles from the mines. The drafted workers were expected to find their own transportation to the mines and to bring their own food. It is no surprise that service in the mines was the most hated imposition of the Spanish conquerors. To save their children from service in the mines, Indian mothers sometimes broke the children’s bones so that they grew up crippled.

➤ THE DESTRUCTION OF THE INDIES, A SPANISH ACCOUNT

The Spanish conquest of the Western Hemisphere led to the deaths of millions of indigenous Americans. Historians and demographers disagree on exact figures and specific causes, but they concur on the effects played by large massacres, harsh exploitation, and, most significantly, the effects of “virgin soil” epidemics, or diseases that devastated peoples who lacked immunity through prior exposure to them. The massive human toll of the Spanish invasion of the Americas was first denounced by the Dominican friar Bartolomé de las Casas, an advocate of the abolition of Indian slavery. Father Las Casas, who expressed an idealized and paternalistic view of the conquered people, was also aware of the vulnerability of the indigenous populations to the diseases that the Spanish brought with them. In his controversial polemic, *An Account, Much Abbreviated of the Destruction of the Indies* (1542), he denounced the exploitation of the native peoples.

“. . . of all the infinite universe of humanity, these people are the most guileless, the most devoid of wickedness and duplicity, the most obedient and faithful to their native masters and to the Spanish Christians whom they serve. . . . These people are the most devoid of rancor, hatreds, or desire for vengeance of any people in the world. And because they are so weak and complaisant, they are less able to endure heavy labor and soon die of no matter what malady. . . .”

—Ana María Kapelusz-Poppi

Source

Bartolomé de las Casas, *An Account, Much Abbreviated of the Destruction of the Indies* (Indianapolis: Hackett Publishing Company, 2003), 28.

As the population diminished in the sixteenth century, the pool of laborers grew smaller, and mine owners were forced to offer more humane conditions. Toward the end of the sixteenth century the laborers were furnished with food and were sometimes given meager pay. By 1606 the mine owners petitioned the

Crown for permission to import African slaves to supplement the Indian labor force in the mines.

Added to forced labor in the mines, the Indians were required to furnish food and textiles for their Spanish masters. Early in the Spanish regime the system that the Spaniards used to govern conquered Muslims in Spain was adopted for the Indians of Peru. The Indians were entrusted to a Spanish trustee (*encomendero*), who was responsible for governing and Christianizing his charges. In return, the Indians of the *encomienda* were required to pay tribute in produce, money, and labor. The Spanish *encomenderos* were commonly extortionate, requiring that the Indian peasants deliver large amounts of their food and textile produce as well as spend much time laboring on the *encomendero's* household and fields. The amount of food produced by the Indian farmers declined with the number the Indian farmers, but the demands of the *encomenderos* did not. Every generation less food was available for consumption by the Indian peasants, resulting in malnutrition and sometimes famine. Thus, the Indian population grew even smaller.

Toward the end of the century as the population shrank, many of the Indian villages became unpopulated or very scantily populated, and the government began to gather the survivors into new villages called *reducciones*. Although most of the *encomiendas* were terminated, their successors, the *repartimientos*, were also very exploitative. Nevertheless, because most of the surviving Indians had developed immunities to the diseases that had killed so many earlier in the sixteenth century, the fierce epidemics ceased to rage, and the Indian population began a slow increase.

Spread of Invasive Species

Invasive species are exotic species that cause damage of some type in their new locations. Thus, they are species that have overcome some geographic barrier (such as a mountain range, a desert, or an ocean) to get to a new place and have managed to survive there well enough to reproduce and spread beyond human control. To be invasive rather than just exotic, species must also cause damage of some kind, even if that is no more than damage to an ecosystem by replacing a native species and causing its decline. The term “invasive species” cannot include native species even if changed circumstances have made them problematic. Between 1450 and 1770 a great many species migrated as a result of humans traveling to new places, but not all such exotic species are considered invasive; only those that damage the health of humans, of other animals, of plants, or of their new environments are considered to be invasive.

Long before 1450, human movement across geographical barriers had led to the movement of species into areas in which they were not found naturally, but the increasing size and speed of ships being developed by Europeans from 1300 on greatly increased species exchange. More space on board ship greatly increased the number of passenger and stowaway species that could travel, and quicker trips meant that more species survived to reach their destinations. As a result, species exchange among Europe, Asia, and Africa increased.

The redistribution of species within the Old World was significant, but after 1492 the redistribution of species became a global phenomenon. Columbus's voyage across the Atlantic led to links being formed between parts of the world that had been biologically isolated and had developed a vast array of different species. The quickening ties between the New World and the Old World in the wake of Columbus led to a reshuffling of species now known as the Columbian Exchange.

Species exchanges began from the very first voyage made by Columbus, and among some of

the most significant invasive species were infectious diseases. It has recently been recognized that strains of syphilis originated in the Americas and traveled on Columbus's ships to Europe, where they quickly began having disastrous consequences for human health. Soon afterward the New World was devastated by invasive species of European diseases, which over time killed the majority of the population. Firm ties were established between Africa and the Americas as the transatlantic slave trade developed. As a result, diseases such as yellow fever and malaria, with their accompanying mosquito species, traveled from Africa to the New World and became established there.

Other species were deliberately introduced in the Americas by the Europeans. Thousands of feral horses were present on the Argentinean pampas by the late 1500s, and by the 1740s feral horses had spread to the tip of South America and to the Great Plains of North America. The effects of these early species introductions are difficult to unravel, but in the case of the horse it changed numerous American Indian societies as they took advantage of this new resource. Other species of livestock, particularly pigs and cattle, also ran wild soon after being brought to the Americas, and the presence of new species of livestock altered ecosystems across the two continents. The invasive species themselves altered in response to their environments to become distinctively American animals. They also opened the way for invasive species of pasture plants, brought deliberately or accidentally from the Old World. Less spectacular invasions also occurred as the planet's biological makeup was irrevocably altered even before the age of mechanized transportation.

Native species may have evolved to match their environment, but they were often displaced by invasive species. This is not because they were inferior to exotic species but because newly arrived species have a number of advantages. Introduced species are often benefited by leaving behind predators or parasites that keep them under control in their origin environment. They may also spread by making unsustainable use of resources in their new region, going through a boom and bust cycle that leaves their new environments impoverished.

➤ THE ARRIVAL OF THE BLUE MUSSEL

The Blue Mussel (*Mytilus galloprovincialis*), native to the Mediterranean, Black, and Adriatic seas in the Old World, has long been found elsewhere. It is unclear whether it is also native to the coasts of France, Britain, and Ireland or whether it invaded there so long ago that it has become part of the ecosystem.

Mussels travel by attaching themselves to ships or by being included in ballast. By treating a ship as a floating island, mussels have long been able to cross ocean barriers that would kill them on their own. Blue Mussels are often found in the communities of organisms that attach themselves to ships, and by hitching a ride on European ships the mussel had managed to invade the east coast of South America by the early 1500s. Traveling in the same way, mussels later invaded Australian, Californian, Russian, Chinese, Japanese, and New Zealand waters.

The Blue Mussel is typical of invasive species that have been present for a long time. It has become an important food source for humans and is so integrated into its new environment that it is generally perceived as native. Only its invasion of South African waters in the 1980s raised questions about its status in North American waters, where it has successfully replaced truly native species of mussels.

—Claire Brennan

But most importantly, invasive species tend to thrive on disruption. Weeds (which if nonnative are invasive species) are most successful on disturbed ground, and plants are often defined as weedy because they will quickly take over disturbed areas. Often species that are invasive in cleared areas could not survive in undisturbed native forest. The spread of invasive plant species in the Americas was helped by the changes being wrought by European people and animal species and by the increasing development that occurred as the food supplies created by the Columbian Exchange increased human numbers and economic activities around the world.

The Pacific Islands had already experienced the introduction of some invasive species in the period before 1450, brought by their original human settlers. At the very end of this period the

start of a new and overwhelming period of biological exchange also reached them. Long before settlement by European people in this region, the ships of explorers seeded the islands with exotic species, among them invasive species. As soon as European ships reached shore, the Pacific Islanders were exposed to new and invasive diseases. In addition, explorers were interested in creating supplies of food for shipwrecked sailors and in sharing the useful species of Europe. While their attempts to introduce species were often unsuccessful, some invasive species managed to establish themselves. Captain Cook is credited with introducing pigs to New Zealand in 1769.

Despite the significance of invasive species in this period, the process of remaking the biology of the planet was not complete. In this period the spread of invasive species was relatively slow. Ports and well-traveled routes tended to be home to species that had just hitched a ride there, but away from the coast and in places with large European settlements, native species predominated still.

—Claire Brennan

Ecological and Biological Exchanges in Oceania

Sustained contact between Europeans and the peoples of Oceania did not occur in the Pacific until after the 1770s. However, those foreigners who did venture into the Pacific prior to that

time brought with them many forms of biological and ecological exchange that would have an enduring impact on Pacific islanders. Indeed, every visitor to the Pacific Islands has brought some form of change. The very first migrants who came into and settled the islands of the Pacific and became the peoples of Oceania introduced new flora and fauna to the region. Archaeological evidence asserts that Oceania's first human inhabitants brought about rapid and significant ecological changes as they established themselves. They altered their environments and developed their complex societies to suit their needs, yet as island cultures they were aware of that environment, their dependence upon it, and the delicate balance that it demanded in order to maintain their resources and well-being. Over centuries of migration, settlement, and development, most Pacific island societies struck a balance with their environment that allowed them to maintain ecosystems and minimize disease experiences. Success required intelligent land management and strenuous labor, and their ecological relationship was established as they struggled against natural hazards and competed with one another over resources.

When Europeans first ventured into the Pacific at the end of the fifteenth century, they also brought new flora and fauna with them, but these foreigners and their foreign species were vastly different from what had evolved in the Pacific region. European ecological relationships differed from those of islanders, and when these two sets of human communities confronted one another the landscape of the Pacific Islands began to be transformed. These new introductions caused many disruptive and often dramatic changes to the physical and social environment, allowed opportunities for foreign microorganisms to find new hosts (animal or human), and initiated epidemics as well as ecological changes.

In 1509 the Portuguese explorer Diogo Lopes de Sequeira became the first European to view the Pacific, but it was the Portuguese voyager Ferdinand Magellan (sailing for the Spanish king, Holy Roman Emperor Charles V) and his Spanish crew on five ships who were the first Europeans to cross the Pacific, landing in Guam in 1521. The Chamorro of Guam thus became the first Pacific islanders to encounter Europeans. When

the Chamorro attempted to take a skiff from the Spaniards, a large landing party attacked and killed many of the islanders, burned nearly 50 houses, and destroyed several canoes.

Despite their role in opening up the Pacific, Spanish interest in Oceania remained relatively minor. However, the vast ocean did serve as a highway for the Spanish galleons, connecting the markets of Acapulco, Mexico, with those of the Philippines. Spanish explorers did come upon many island groups and by the late 1600s had visited several of the archipelagos of Micronesia. In the 1680s Spanish forces and Jesuit missionaries moved all Chamorro from their remote villages on Guam, Rota, and Saipan to settlements closer to the mission. Within a generation, the Chamorro population dropped from approximately 70,000 to 20,000, most having fallen to newly introduced foreign diseases for which these islanders had no immunity.

Micronesia remained under Spanish hegemony until the late 1800s, but the remainder of the Pacific experienced a variety of encounters with Portuguese, Dutch, British, and French explorers—the Portuguese dominating the sixteenth century, the Dutch dominating the seventeenth century, and the British dominating the eighteenth century—all largely pursuing commercial ventures. As with Micronesia, these early encounters between Europeans and communities in other parts of the Pacific brought previously unknown diseases into Oceania and resulted in dire consequences for Pacific islanders. For example, the Dutch navigator Jacob Roggeveen encountered Rapa Nui in 1722 and named it Easter Island to mark the day of his arrival. Roggeveen and his crew anchored off the island for a week. About 150 men went ashore for a day, introducing venereal diseases to the

islanders and accelerating rates of depopulation. By the early 1800s ships' captains rarely landed at Rapa Nui because syphilis was so prevalent.

The arrival of the British crew led by Samuel Wallis in Tahiti in June 1767 and the French reports that followed, thanks to the visit of Louis de Bougainville eight months later, captured European imaginations and led many others, including James Cook, to follow and center their attention on the Pacific. The "discovery" of Tahiti would open a new era in European explorations of the Pacific, but even these first visits brought new infections (venereal diseases) to these islands.

It is thought that over 400 European ships crossed the Pacific from 1520 to 1770, but their impact on the islands of Oceania was minimal as compared to the post-1770 era. Certainly when Europeans first ventured into the Pacific they brought with them many changes, including the introduction of diseases that were until that time foreign to the peoples of Oceania. While there were notable encounters between islanders and Europeans prior to 1770, it would not be until after that time that European ventures into the Pacific became much more sustained and the resulting biological and ecological (ex)changes increased dramatically.

■ Introduction: Human Environmental Impact

The effect of climate and geography on human history is apparent, although details are widely debated. Nevertheless, human settlements and their development were shaped by geographic and climatic factors, including

soil type, rainfall, and presence of natural resources. Yet we must also keep in mind the capacity of human beings to impose themselves on their environment and to transform it to their needs in defiance of the natural world. They

drained swamps, cut down trees, dug canals, and leveled mountains. In the New World, Europeans, using slave labor, constructed vast plantations that cultivated monocrops (e.g., sugarcane, tobacco, etc.), transforming the natural environment in Brazil and the Caribbean islands. In Iran, irrigation systems allowed cultivation of land in what used to be arid regions of the Iranian plateau, while heavy dependence on rice caused the spread of flooded fields throughout Southeast Asia. At the same time, the profitable fur trade in Siberia and North America led to the rapid extinction of some species as humans hunted them for their furs. Increasing human populations also had a profound effect on fish populations.

Cities and Gardens in the Muslim World

Urban landscapes in the Muslim world are versatile in form, function, and style. They differ in time and space but combine unique elements that make them Islamic. Although the typology offers a variety of terms, names, and definitions ranging from oriental and Arabic to Muslim and exotic, cities and their surroundings in Islamic countries share distinct common features. Looking at the Muslim world in a specific time period, 1450–1770, we are able to exclude some regional aspects and focus on other areas. During this time period, the Muslim world was dominated by large empires in the Middle East and Southeast Asia, the Ottomans, the Safavids, and the Moghuls. All were known for a strong and powerful central authority that ruled the land from their capitals and major urban centers. Cities like Istanbul, Cairo, Isfahan, and Agra are just a few samples for the expression of Muslim power and civilization through large sophisticated and developed urban landscapes. Islamic architecture is heavily influenced by religion, culture, and daily necessities. Local styles were further exposed to outside forces and impressions. The architecture of the Mughals has been affected by other, mostly Hindu, influences. North African buildings clearly depict Roman-Greek-Byzantine elements, while Turkish-Ottoman landscapes developed their own characteristic style.

While it is impossible to simply call a city Islamic, it makes more sense to highlight the influence of Islam on urban life. Islam was born as an urban religion with Mecca and Medina as the two holiest cities. At times an idealistic concept of a Muslim city was developed, and sample cities such as Medina or Baghdad were selected. But landscapes changed frequently over time: what once was considered a garrison town turned into a classical or oriental model. Fortifications were added, and rulers sought protection behind large citadel walls until they restored power or they realized how quickly gun power can penetrate even the thickest wall. With rising power and status, the ruling elite, which often was foreign to the urban population, was able to move beyond the city and wall limits into gardens and pavilions. This left the growing segments of the city in charge of their own protection and development. In reality the quarter of the city, the alley, and the single house became an imitation of the ruler's city as a whole.

Besides the residential quarters, medieval and premodern Islamic cities combined additional architectural features: religious buildings (mosques, Quran schools, endowments, and shrines), economical institutions (khan, markets, and factories), and administrative structures (palaces, courts, citadels, fortifications). They mirror the dualistic concept of Muslim urban structure, where the private and public domains are clearly separated. Residential quarters were then further divided along ethnic and sometimes religious lines.

Buildings and structures related to water supply of the cities have been impacted by Islam as well. Muslim rulers provided access to fresh water through cisterns, canals, and wells. Over time they were converted into private property mostly through legal regulations and inheritance. Water supply for gardens and fields was also highly regulated and regarded as a powerful tool in the hands of the owner. From an aesthetic perspective, one could argue that water was celebrated as a source of life and a symbol of the afterlife, with qualities that were based on poetry, a special genre of poetry, the *rawdīyat* or Garden Poetry. The architecture of gardens thus was considered an intersection of intellectual, religious, and functional design.

► ISFAHAN—THE CREATION OF THE SAFAVID CAPITAL

The city of Isfahan was not founded by the Safavids; it existed long before their dynasty came to power. But with the Safavid conquest in 1502, Isfahan became one of the largest and most beautiful urban landscapes in the Middle East. At its peak, the city had a population of over half a million and was the capital of an empire that stretched far beyond the borders of present-day Iran. The Safavids started an ambitious building program with bazaars, shops, mosques, libraries, and, most notably, gardens and parks. Shah Abbas brought skilled craftsmen and artists from all over the empire to the “middle of the world” (*nesf-e jahan*, Isfahan in Persian), among them Christian Armenians who constituted an important segment of the diverse population and cultural tradition of the city.

The city’s public landscape included large sacred buildings around the Imam Square with their typical three-walled vaulted halls (*Iwan*) as well as a network of gardens for both the public and the ruler. These gardens were built around the Zayandeh Rud River and connected the different quarters of the city. Wide and open boulevards, long bridges, caravanserais, baths, and markets as well as mosques and churches shaped the architectural layout of the city. Trade, manufacturing, and agriculture flourished during the golden age of the city that lasted for 200 years until 1722, when it fell to Sunni Afghans. However, the unique master plan, drafted by the Safavids, is still visible today.

—Sebastian Maisel

But gardens in general provided urban elites with a luxurious space to set up seasonal residence as well as an additional display of glory and power. The most common types included urban enclosures, larger suburban gardens, and more natural hunting resorts. Rulers of all dynasties, the Ottomans, Safavids, and Mughals, spent significant time in their gardens; some even took permanent residence there. This led to the creation of entire garden cities, where rulers sometimes sought refuge from internal power rivals.

Mughal emperors like Babur and Jahangir followed the tradition of building expansive garden cities that was started by Timur in Samarqand. One of the most intricate and impressive examples was the Taj Mahal in Agra built by Emperor Jahan. The Safavid shahs in Persia concurrently started an enormous building program in and around their capital of Isfahan. One can go as far as saying that the entire history of the Safavids, starting with Ismail and Abbas and ending with Sultan Hussain, passed through their gardens, where many contributed additional gardens spaces or expanded existing ones. Although the Ottoman sultans show similarities with European gardens, they still were mostly known as a place of retreat for mystical practices and exercise of power.

China’s Fifteenth-Century Agricultural Plateau

Chinese civilization, as with all preindustrial civilizations, was predominantly agricultural. The vast majority of the population was farmers, living in rural villages. Since before the Han dynasty, Chinese agriculture was the most productive, supporting the largest population in the world. Chinese agriculture was so productive because the Chinese farmers invested a great amount of intensive labor, grew a wide variety of crops, and led the world in the development of agricultural technology until the eighteenth century.

In the warm and relatively wet climate of the Medieval Warm period (ca. eighth to fourteenth centuries), agricultural productivity continuously

increased, and the population grew. The pressure of the population on the available land increased. During the fourteenth century, with the beginning of the Little Ice Age (fourteenth to mid-nineteenth centuries), the weather turned colder, and droughts (perversely interspersed by massive floods) became more frequent and lasted longer. Chinese farmers reacted to these adverse circumstances by increasingly using drought- and cold-resistant technology, but by the mid-fifteenth century this development reached a plateau, and food production failed to keep up with the population increase. Few new food crops were introduced after that of Champa rice in the Song dynasty; crop failures increased, as did famines, infanticide, and occasional cannibalism. After the transition from the Ming to the Qing dynasties (1644), Chinese agriculture experienced a remarkable increase in productivity, partly because of the widespread adoption of food crops from the Americas.

Political and economic contingencies acted with the deteriorating climate to produce the agricultural crisis of the late Ming. As in other dynastic changes, the wars accompanying the fall of the Yuan (Mongol) and the rise of the Ming dynasties (1368) produced devastation and some depopulation of the countryside, especially in northern China. The Ming triumph resulted in a vigorous new dynasty free of the corruption of the departed power and able to take drastic action that long-established regimes, encumbered with a multitude of special interests, could not. The young Ming dynasty redistributed some of the land, reduced some of the burdens of the peasantry, established law and order, suppressed banditry, vigorously took measures to control floods, and improved the infrastructure of roads and canals. Under the early Ming the peasantry, and with it the nation, thrived, and the population is estimated to have nearly doubled from 100 million to 200 million. The urban population increased, placing large demands on the countryside not only for food but also for nonfood crops such as tea, silk, and cotton (which had been introduced into China in the Song dynasty).

While the cultivated land increased at a much slower pace than the population, the proportion of the cultivated area devoted to food production declined. The demand for cash crops, especially

cotton, expanded greatly. The most productive areas of China were becoming commercialized, and consequently by the middle of the Ming dynasty, food was becoming more expensive. In the wheat- and millet-growing northern plains, the land was often held in large estates, worked by wage labor or bond servants, whereas in the wetter and more mountainous south, more of the land was farmed in small plots by tenants whose landlords increasingly demanded their rent payments in money rather than in kind. The consequence of these kinds of land holding was a premium placed on the production of cash crops rather than subsistence.

The evolution of agricultural taxes also encouraged the production of nonfood cash crops, to the detriment of subsistence crops. The Ming dynasty, like all dynasties, was largely supported by agricultural taxes, which bore heavily on the peasants. Originally the peasants were taxed in crops and labor. The crops were often rice and wheat, but other crops were also taxed. The labor was used for flood-control and irrigation projects, the construction of canals, and especially the Great Wall of China. (There had been defensive walls before the Ming, but the Ming built the Great Wall, constructed of stone, as we know it.) The peasants hated the labor tax (*corvée*) and opted to pay in money for a substitute. By the middle of the dynasty, most of the *corvée* was commuted into cash. Increasingly, the tax in crops was also collected in cash. By 1581 under the terms of the Single Whip Reform, all taxes were collected in cash. To pay these taxes, the peasants had to devote more and more land and labor to cash crops and less to subsistence.

In spite of the deteriorating climate regime and the population to land ratio, Chinese farmers were able to feed the nation in good years. Chinese farmers conserved moisture by pit farming, that is, growing their plants in individual pits and carefully hand watering each plant. Increasingly, especially in northern China, crops would be planted between furrows, which protected the plants from frost as well as preserving moisture. But even these measures, which required backbreaking labor, proved insufficient in the mid-sixteenth century, when ice appeared in the Yangtze delta and snow dusted the rice paddies of southern China.

To add to the woes of the peasants, the flood-control and irrigation works that every Chinese government must make a high priority came to be neglected as the taxes paid for their maintenance were embezzled by venial officials. Normal flooding became disastrous, and famine again visited an already malnourished people. Deep poverty, starvation, voluntary enslavement, crime, and banditry emerged as justice and law were sacrificed to the increasingly frantic Ming government's search for cash.

The agricultural plateau, which had been reached in the late fifteenth century, affected the rest of the economy by the mid-sixteenth century and became a trough instead of a plateau by the economic crisis of the early seventeenth century.

Shaping the Land in Teahouse Japan

The Japanese teahouse in its relatively final shape emerged in the sixteenth century as a site for holding tea ceremonies incorporating the philosophy and aesthetics of Zen Buddhism. The tea ceremony itself was developed as a means of spiritual cultivation through the mastering of highly sophisticated etiquette. Fire and war constitute Japan's political history from the fourteenth century to the beginning of the seventeenth century; however, it was during this period that the arts, including the tea ceremony, progressed at a greater rate than at any other time. The architectural style of the Japanese teahouse is one of the two chief traditional

styles surviving, albeit in more refined forms, in Japanese residential architecture today.

Until the end of the nineteenth century, the tea ceremony was a pastime for men only. Its origins are traced to ancient China, where it was influenced by both Taoism and Confucianism. Tea is believed to have been first imported from China to Japan during the regency of Prince Shotoku (574-622). However, the cultivation of tea did not catch on very readily in Japan, and although tea was used for medicinal purposes by the nobility, after the tenth century, even this practice died out, and tea drinking disappeared from Japan.

In 1191 the priest Eisai (1141-1215) returned from China and introduced the Zen sect of the Rinzai lineage to Japan. He also brought tea seeds and attempted to use tea as a tool for propagating Zen. As the availability of tea increased, more and more court nobles and families of high rank began to drink it, primarily as a refreshment. By the fourteenth century tea drinking had spread from court nobles to the warrior class and even to some commoners. At this time tea gatherings centered around a contest in which stakes were wagered and participants vied with one another to distinguish different teas by taste.

Simultaneously, tea drinking was developing into a solemn ceremony at Buddhist temples. The process was becoming more and more systematized, although it never acquired any meaning other than as an auxiliary function for monastery life. The Buddhist tea ceremonies were characterized by exclusive use of utensils and decorations imported from China. The fascination with things Chinese spread to the upper classes of society, whose tea gatherings turned into luxurious entertainment.

The prototype for the Japanese teahouse as we know it today was designed by Murata Shuko (1423-1502) as a reaction to the lavish tea gatherings of the upper classes. It was the austerity and simplicity of Zen Buddhism that led Shuko to serve tea to a limited number of guests in a small room of only 9 square feet (.8 square meters), largely relying on Japanese utensils and settings that were intentionally made imperfect. Shuko also originated the idea of the host personally serving tea. In the period of incessant civil wars and unrest, Shuko's simple style gradually gained more and more popularity.

► SHOIN STYLE AND SUKIYA GARDENS

The *shoin*-style gardens were generally designed to be viewed from a seated position in the building interior and thus were directly correlated to the function and style of the architecture. There are no other known examples of this kind of correlation in other cultures.

In contrast, in the late sixteenth century when the tea ceremony and teahouse became accomplished, the small *sukiya* (teahouse) garden was designed for walking through and concentrating one's attention on the way to the site of the tea ceremony. The designers realized that a person's attention can be manipulated by controlling movement in garden interpretations.

Thus, a number of hide-and-reveal techniques (*miegakure*) were developed to configure garden scenes in sequence as visitors walk through a teahouse garden. Effects are created that provide a sense of depth and pique the viewer's expectations of the next scene by, for instance, interrupting lines of sight, concealing the depth of the site, and obscuring the overall view. In principle, no element of the walkway of a teahouse garden is shown in its entirety.

At the same time, teahouse gardens usually do not have spectacular views and bright colors. They are a means of escape, a transition between the distractions of daily life and the solitude of the tearoom.

—Anatoliy Anshin

Yet it was Sen-no Rikyu (1522–1591) who brought both the tea ceremony and its site, the teahouse, to the peak of refinement. Rikyu codified the rules of etiquette and the Zen-based aesthetic principles of the ceremony and its settings. The principles were harmony (*wa*), respect (*kei*), purity (*sei*), and tranquility (*jaku*). Harmony is the oneness of host and guest with the flowing rhythms of nature. Respect is the sincerity of heart that allows one to have an open relationship with the other participants, humbly recognizing their dignity. Purity is removing the dust of the world from one's heart and mind. Tranquility comes with the constant practice of harmony, respect, and purity in everyday life. It should be noted, however, that all

of this was achieved only through a discipline of body and mind.

Rikyu also introduced changes that served to level the social distinctions in the tea ceremony. He made the main entrance of the teahouse so small that one had to double up and crawl through. By this method Rikyu placed all participants on an equal footing, allowing no nobility, no commoner, to be distinguished in the manner of service.

Thus, the confined, austere teahouse, ornamented with only a hanging scroll and a single flower in a container beneath, was turned into a sanctuary where one could take solace in the tranquility of spirit. Its simple and natural design with a look of temporariness and subtle beauty was conducive to reflection and introspection. Its intent was to strip the individual of his worldly cares and transpose him into an environment where, through participation in a tea gathering, he could cleanse his thoughts of the mundane and unimportant.

It is essential to mention that no effort was made, until Rikyu's day, to free Japanese architecture from its limitations and to achieve a beauty of design independent of social and religious symbolism. Rikyu's teahouse style was the first to give free rein to creative energy and originality of design. It was the small and modest teahouse that gave Japanese architectural design its first opportunity to escape from its bondage to religion and a rigid social order. Rikyu's teahouse style itself, however, did not settle into a fixed pattern for a long time. It was not until about the middle of the eighteenth century that the idea of preserving teahouse forms with uncompromising strictness took hold.

After Tokugawa Ieyasu (1542–1616) completed the unification of Japan in 1603 and peace prevailed in the country, Rikyu's descendants continued to propagate his style of tea ceremony among the warrior and merchant classes alike. However, Rikyu's liberal spirit was pushed aside by the demands of the new era. The change from Buddhist to Confucian thought with its heavy emphasis on strict social hierarchy was effected by the first Tokugawa rulers, and the tea ceremony was influenced in the same way. The majority of tea ceremony gatherings of the Great Tokugawa Peace came to be characterized by

the explicit social discrimination of their participants and an unrestrained decoration of utensils and settings. This trend endured until the Meiji Restoration (1868), which eventually resulted in the abolishment of social classes and marked the beginning of Japan's modern age.

Driven to Extinction— The Siberian Fur Trade

Russian expansion into Siberia greatly expanded in the late sixteenth century and the seventeenth century. This expansion was prompted by the lure of various furs from animals native to Siberia. These furs provided income for the government and individuals through export to western Europe, but increasing Russian colonization of Siberia led to a decline among the native population. The desire for greater numbers of furs also caused the fur-bearing animal population to nearly disappear, with significant ecological consequences for Siberia.

Medieval Novgorod was a center of fur trade for much of Europe but lost its dominance in the fifteenth century to Moscow. As fur-bearing animals declined in western Russia, trappers and traders sought new sources to the east. By the last half of the sixteenth century, traders had crossed the Ural Mountains and establish trading

posts. Powerful commercial interests, particularly the Stroganov family, received charters to develop trading networks in Siberia. They were allowed to raise private armies with cannons and to build forts to protect their interests from the native people and the khanate of Siberia. In July 1580 a Cossack army invaded territory claimed by the khanate and captured the capital of Isker by 1582.

Although fighting against the khanate continued until 1598, the Cossacks' success encouraged the tsar's government and other groups to send more expeditions to exploit Siberia's riches. The Russian government quickly established control over the region, which was divided into regions ruled by military governors. These areas were divided into smaller units, and the native people living in each unit were ordered to pay an annual tax known as the *yasak*. The *yasak* was paid with pelts, consisting of 5 to 12 sable furs for each man. If sables were not available, pelts from lesser animals were substituted according to a rate established by the Russian government. Russian officials held hostages from local tribes, ensuring that the *yasak* would be paid.

Most furs collected in Siberia, however, were brought out by teams of hunters and trappers known as the *promyshlenniki*. The *promyshlenniki* were either groups of men connected by family ties or men hired by commercial interests to catch fur-bearing animals. By the early seventeenth century at least 1,000 *promyshlenniki* were active in Siberia each year. The number continued to increase annually through the remainder of the century. A typical hunting expedition took two years because of the extensive travel required. Customhouses were established by the Russian government along travel routes to check the furs collected by the *promyshlenniki* and being returned to European Russia. One of every 10 pelts was taken as taxes, and the remaining furs were divided among the hunters. If they received fewer than 20 sable pelts as their share, the expedition was generally considered a failure. During good years an individual might receive between 120 and 280 furs.

The fur most in demand in Russia and Europe was the sable. Sables were carnivores that lived in the Siberian forests. They were solitary animals that established their own territory.

Although the size of these territories varied according to the prey available, the sable rarely left. Gestation of young sables took up to 300 days. During the winter sables established a permanent burrow, making it easy for hunters to locate them. Other than humans, sables had few natural enemies.

Before the Russian occupation of Siberia, the natives hunted fur-bearing animals only for their own consumption and for limited trade. Demands of the yasak required them to obtain more pelts than they had previously obtained. Native hunting helped deplete the sable and other fur-bearing populations, but its effect was limited by their use of only bows and arrows. Russian hunting was much more devastating. The promyshlenniki also used bows and arrows with blunt tips that would not harm the fur. However, they used stationary traps as well. Individual hunters built up to 30 traps each and positioned them in areas that the sables were likely to frequent during the summer and fall. The trapline was checked each day, and dead animals were removed and processed. After heavy snow fell, the promyshlenniki located sable burrows by following footprints in the snow. The hunters surrounded the entrance with a net and waited until the animals emerged and became tangled up and then killed them. Hunts were aided by dogs that could sniff out sables and other animals.

Foreign demand and the desire for profits led to rapid depletion of the animal populations. Slow-reproducing animals disappeared from wide areas of Siberia. When sables became less common, hunters turned to foxes, squirrels, and beavers for their pelts. As a region became hunted out, the promyshlenniki moved farther to the east looking for new populations. Eventually Russian hunters and government officials reached the Pacific Ocean and crossed to North America in search of furs.

The extinction of sables and other fur-bearing animals led some Russians to establish agricultural settlements. The native population, on the other hand, was devastated by the destruction of their traditional way of life and declined. Although much of Siberia remained a wilderness, the hunt for furs had brought it firmly under Russian control.

Canal Building in Europe

The mastery of water as a resource is a fundamental principle to the building of European states in early modern history, just as it was important to ancient civilizations. In every age of history, people have considered the role of water as important as mastery of the land itself, whether used for agricultural purposes, commerce and transportation, or military ends. One of the ways in which humans have demonstrated their mastery of water as both a resource and a tool for building societies is in the building of canals. Canals are artificial waterways that are engineered and built for drainage and irrigation of the land or for use as a means of navigation to serve a variety of social, political, military, and economic functions. The building of canals for agricultural irrigation and for drinking water is a practice that has ancient origins, as control of water was an essential part of the earliest known civilizations of Mesopotamia and Egypt in the Near East. However, the Chinese are generally credited with making the most significant early historical advancements in design engineering that made canal construction possible. The major canals of history have usually been constructed as open land excavations, done by manual labor long before the age of machinery. In the earliest canals, it was most common to use natural existing waterways, such as rivers, to augment the design.

A necessary requirement for canal construction, beyond the accessibility of a direct water source, is the means to maintain water levels. Therefore, before the industrial age, the regions of the world that constructed canals were those that had the advantage of level topography. This

was because the practice of building locks to equalize the flow and level of water had not yet been sufficiently developed, and the movement of water through different land levels made the transport of vessels impossible. The idea of the lock is believed to be the contribution of a Chinese engineer, Chiao Wei-yo, whose works date to the tenth century. The introduction of locks throughout Europe between 1400 and 1600 caused a proliferation of canal construction during that time period, primarily for economic and military purposes. Major shifts in water levels, once a hindrance to effective canal building, now became a conquered challenge with the invention of the Chinese flash lock, which operated with a single gate. This was generally considered unsafe, so the improved version that appeared in Renaissance Europe featured two gates. The result is what is known as the pound lock, which soon became standard on all canals built. The first of these to be used in Europe is believed to be in the Netherlands and probably dates to the fourteenth century.

At first these gates involved significant amounts of manual labor, as the barrier created by the first canal gates was simply raised and lowered to allow vessels through. Because engineers also faced the challenge of strong water pressure against these early gates, further advances were necessary to make their use more efficient.

The introduction of the miter lock gate solved many of these early difficulties. This design involves a system whereby each end of the lock contains wooden gates that remain slightly ajar but are held together by the work of the water pressure. When the level of the water reaches the same height on each side of the gate, the gate can then be opened easily without the laborious efforts required in earlier locks. The first such lock was used in Italy about 1500, in the city of Milan, and proved to effectively address the challenge of joining two previously constructed waterways with varying water levels. This became known as the San Marco lock, which many scholars believe to be from an original design by the noted Renaissance artist and engineer Leonardo da Vinci. At this time in history, da Vinci was in the service of the duke of Milan. Not surprisingly, these significant advances in water-control ability spurred various European nations

➤ CANAL BUILDING IN THE NETHERLANDS

Canal building found exemplary expression in the Netherlands, where such waterways were crucial to economic health. Following the collapse of the western Roman empire, canal building became a lost practice as Europe entered the Middle Ages until the Dutch revived it beginning in the thirteenth century. Because of the critical link between the use of water transport and the booming commercial trade of the late Middle Ages, the Dutch were leaders in advancing canal engineering design. There was a boom in canal construction in the Netherlands during the seventeenth century in what is known as the Dutch Golden Age. Unlike other European states at the same time, the Dutch concentrated the majority of canals within major cities, including the most striking examples in Amsterdam. The four major canals of Amsterdam include the Herengracht, Prinsengracht, and Keizersgracht, which are collectively known as the Grachtengordel and were developed primarily for residential purposes. The fourth major canal of Amsterdam is the Stadhouderskade, which served primarily defense functions for the city. All of these major canals played an important role in making the city and its trade traffic accessible, aiding the rise of the Netherlands to great economic status as the major commercial center of Europe.

—Cheryl H. White

to invest in further development. The peak of canal building in Europe coincided with the opening of the Age of Exploration and Discovery, when the nations of Europe began competing for control of new resources derived from new open markets.

Earlier examples of canal construction served as important model efforts to men working to perfect inland waterways. Two of the most important such contributions originated in the Middle Ages and included the Naviglio Grande Canale in Italy, constructed in the twelfth century, and the Stecknitz Canal in Germany of the fourteenth century. Over the next centuries France also perfected canal waterway expansion, completing the Briare Canal in 1642 that was built to join the Loire and Seine rivers. This was a particularly notable achievement in design, as it features a steep level change that

incorporated six consecutive locks. The Canal du Midi, finished in 1681, was constructed to join the Atlantic Ocean to the Mediterranean Sea and represents another engineering marvel for the age. The Canal du Midi employs three aqueducts and makes a steep descent, which would have been unthinkable two centuries before.

These significant engineering advancements on the continent of Europe stimulated Great Britain to pursue similar design and construction. There, the Bridgewater Canal of 1759 became the first in Britain to run independently of a river and proved highly useful in the transport of coal during the Industrial Age. By this time, the purpose of waterway canals was primarily economic and soon became an indispensable means of transporting raw materials and finished goods throughout Europe. In the commercial and industrial age, canal construction represented another means of economic competition among European states as efficient and rapid transport became an increasingly important factor in economic domination.

Advance of the Three Sisters— Agricultural Revolution in the Americas

Native American peoples, ranging from Mesoamerica to the eastern coast of North America, referred to corn, beans, and squash as the “three sisters.” James Adair, an Irish trader who published an astute description of the Indians of the Southeast in 1775, described how they planted the three crops together: “They plant the corn in straight rows, putting five or six grains in one hole about two inches [five centimeters] distant . . . [and] in the vacant ground [between the rows] they plant pumpkins . . . and sundry sorts of beans and peas.” These three crops were the mainstay of most tribes’ diet and were the source of much of their nutrition. Corn, beans, and

squash could be planted in the same field with good results, making it easier for farmers to raise them. They also provided abundant harvests with relatively small investments in land and labor, allowing Native American populations to grow larger and permitting permanent settlements.

The earliest examples of domesticated corn, beans, and squash date to around 7000 BCE. Maize was most likely domesticated from a type of wild corn. Early farmers recognized that they could plant seeds and produce dependable harvests on a regular basis. They also practiced careful seed selection to improve the yields of future crops. Native American farmers eventually developed over 700 varieties of corn, ranging from popcorn to sweet corn consumed as a vegetable. Other varieties were grown for their suitability for grinding into flour or their ability to adapt to climatic variations.

The first instances of cultivation were in the Tehuacan Valley in Mexico. From there, the cultivation of corn, beans, and squash spread north and south. The Maya may have been the most important people in spreading these crops, thanks to their extensive trading networks. Corn spread to the future U.S. Southwest, where the Hohokam Indians grew it. They developed varieties that could withstand the heat and dry weather better than the original versions. The Hohokam dug at least 600 miles (960 kilometers) of irrigation canals between circa 50 CE and 450 CE to bring water to their fields. The Anasazi used a flood method of irrigation as well as planting their crops in crevices and at the foot of cliffs, where water naturally tended to collect. Water drained into these low spots and soaked into the ground, where the plants’ roots could absorb it during dry weather.

Cultivation of the three-sisters complex spread eastward and north into those areas that had sufficient moisture and a growing season of at least 120 days. The development of an agricultural system changed the social and cultural patterns of the people, enabling those who adopted agriculture to shift from seminomadic hunting and gathering societies to relatively permanent settlements. Land had to be cleared for fields. Meat obtained through hunting remained important but was no longer central to the Native American diet. Because the harvest from these

crops was usually large, surplus food was often available. Populations grew with a more stable food supply. Corn, beans, and squash could all be dried to preserve them for long periods. Many tribes traded the vegetables with more nomadic tribes for products such as meats, hides, and furs. Washington Matthews, an American military officer during the 1860s, observed how the Dakota carried out trade with the Hidatsa, as they had for generations. The nomadic Dakota learned that when some wildflowers bloomed, corn would be ripe. They approached Hidatsa village with horses, bison meat, and furs for trade. The two groups maintained a truce until after the transactions were completed.

Many of the Native Americans used a system of growing the three crops together. Indians in the Southeast, along the Atlantic coast, and in the Ohio Valley learned from experience that yields were larger, while the labor required to tend the crops was less. Corn seeds were planted in small hills and allowed to germinate. Beans were then planted, and the bean vines used the corn stalks for support. Squash seeds were also planted, and their large leaves shaded the ground, keeping it moist and preventing the growth of many weeds. Although they did not realize it, beans draw nitrogen out of the air and fix it in the ground, where it could be used by the corn and squash. When corn, beans, and squash were consumed as parts of a balanced diet, they provided protein, amino acids such as lysine and tryptophan, and vitamin A and similar nutrients. By the time European settlers arrived in North America, they found large cultivated fields, tended by Indian women. The Europeans adopted the three sisters as central to their diet as well.

The complex took on a religious symbolism for many tribes. Agricultural peoples saw each of the crops as a gift from the gods but also as inseparable. In the creation stories of many tribes, maize in particular assumed prominence as a mother figure, but corn, beans, and squash were recognized, in fact, as three sisters, and festivals celebrated both the plantings and the harvests of the crops. The Iroquois dried the three crops together, and most tribes developed dishes in which corn, beans, and squash were all cooked together. The most famous example was succotash, which New England Indians shared with

early English settlers. Succotash became so common among New England settlers that it is still recognized as a regional culinary specialty.

Driven to Extinction—The North American Fur Trade

From the beginnings of European interest in the North American continent in the early 1500s, the trade in fur pelts motivated relations with the Native Americans, settlement patterns of the colonists, relations among continental powers, and war. By 1608 when Quebec was established as a trading center, French explorers had already begun to trade foreign goods for pelts acquired by the Indians. The Dutch, in founding New Amsterdam in 1625, viewed the potential of the fur trade within the Hudson River watershed as a reason for establishing its center on Manhattan Island. British settlers followed suit in New England and Virginia and through their alliance with the Iroquois federation expanded the trade as far south as Georgia. The wars between Britain and the Dutch (settled in 1674) and the French and Indian War (settled in 1763) were in part fought over which country was to benefit from the lucrative trade in fur.

With permanent settlement along the Atlantic seaboard by the time of the American Revolution, the trade shifted westward to the Ohio and Mississippi watersheds, the Pacific Northwest, and Alaska. The European rage for top hats fueled the beaver market. Following the death in 1779 of Captain James Cook during his third expedition to the Pacific, the crew sailed to Canton and discovered that the Chinese aristocracy coveted the sea otters acquired at Nootka on Vancouver Island.

With movement westward, the fur trade was still tied to diplomacy. Beavers, sea otters, and

Native Americans bring beaver skins to European traders, seventeenth century. (The Print Collector/StockphotoPro)

other animals became tools of foreign policy by Great Britain, Spain, Russia, and the United States as each vied for both the possession of the continent and its rich resources. The 1789 Nootka controversy, whereby Spain attempted to claim a trade monopoly along the Pacific coast and seized British ships, was emblematic of the competition. Between 1790 and 1794 Spain and Great Britain signed three Nootka Conventions that led to free trade in the region. Following the agreements, the run on otter and beaver pelts assumed gigantic proportions.

Exploration was also uniquely tied to the fur trade. British and Canadian fur concerns, notably the Hudson's Bay Company (established by Parliament in 1670), followed the beaver from the Atlantic Ocean to the Pacific Ocean and charted the river systems located within their domain. Spanish mountain men traveled north from Mexico and joined those from the United States working their way into the farthest reaches of the Rockies. Russian traders, whose colonies in Alaska were well established by the time of Cook's final voyage, chased the sea otter as far south as San Francisco Bay. From Boston, Captain Robert Gray, commanding the *Columbia* and the *Lady Washington* on a fur-trading venture to the northwest coast in 1789 and 1790, established the first U.S. claim to the region. After Lewis and Clark's Corps of Discovery publicized the results of its two-year overland journey (1804–1806), American trappers expanded their

domain into the Pacific Northwest. Astoria, John Jacob Astor's fur-trading post at the mouth of the Columbia, was one of the earliest attempts to establish a permanent settlement in what became Oregon Territory.

Native Americans supplied the beaver and otter pelts, and Euro-Americans sought trade alliances with the Indians living in those areas where furs were abundant. In some instances the associations produced strong cultural ties between Native Americans and Europeans as they met each other at the yearly rendezvous. French Canadians married Indian women, producing a new culture of Métis, for example, who settled throughout the fur-trading region. Other societies welcomed the trading items, and newer technologies provided in exchange for furs. Indians had already established continental trading routes in pre-Columbian times, and new traders adapted these routes as they trapped the beaver.

The partnership ultimately proved devastating to Native American tribes. The same trading routes that were used for the beaver trade had also, by the time of the American Revolution, brought smallpox along them. The disease destroyed entire Indian villages throughout the trading network. When British captain George Vancouver explored Puget Sound in 1792, for example, he witnessed both deserted villages and Indians exhibiting the telltale pockmarks left by the disease. Historian Elizabeth Fenn notes that the results observed by Vancouver were the product of an epidemic that began on the Atlantic coast during the American Revolution and moved westward along Native American trading routes. In addition, the influx of a trade that exchanged furs for weapons, alcohol, metals, and other goods escalated conflicts between tribes and further destabilized Native American culture. Indigenous village economies were eroded as native peoples abandoned traditional trading networks to trap fur in exchange for what the traders offered.

Exploitation and extinction of both the resource and Native American cultures followed in the wake of the fur traders. Britain's Hudson's Bay Company wanted to transform the Indians' cultures by both converting them to Christianity and making them dependent upon the company

for their livelihood and supplies. When realizing that portions of its corporate domain were to be ceded to the United States in 1846, the company launched a scorched-earth policy to eliminate all beaver south and east of the Columbia River.

By 1869 when the first railroad crossed the continent, both the beaver and the sea otter were near extinction. After trains began their journeys through the Great Plains, a trade in buffalo hides ensued. Unlike the Plains Indians, who made total use of the animal and killed only what was needed, the new traders killed every buffalo in sight, removed the hides, and left the carcasses behind. While this slaughter practically destroyed both animal herds and the Plains Indians who relied on the creature for survival, by 1883 William “Buffalo Bill” Cody through his Wild West performances was popularizing this destruction as entertainment.

Fashion changes saved the animals from total extinction. The Chinese tired of the otter, and Europeans traded in their beaver hats for silk. Even so, the assumption of resource abundance that had motivated the fur trader from the

beginning continued on in the minds of the fishermen, lumbermen, and miners who followed the fur traders into the American West.

■ Introduction: The Columbian Exchange and Human Adaptation

For thousands of years, humans populating the Western Hemisphere and the Eastern Hemisphere had had no contact. The European Age of Discovery put an end to this mutual isolation and ushered in a new era of contact. An important part in the process was human adaptation to new environments, crops, and animals. Links between the New World and the Old World led to an exchange in food sources, a process known as the Columbian Exchange. The Eastern Hemisphere had wheat, grapes, horses, cows, sheep, and pigs, while the Western Hemisphere supplied potatoes, tomatoes, maize, and tobacco. The Columbian Exchange eventually affected almost every society on earth and improved the quality of life

throughout the globe. In some regions, particularly in China, the new crops, together with agricultural improvements, caused large population increases. Corn, first domesticated in the Americas, became a staple food in Africa, while the potato became widely popular in Europe. Food crops from the Western Hemisphere played a key role in shaping the early modern world, and about 30 percent of the foods consumed in the world today come from the plants indigenous to the Americas. However, not all aspects of the Columbian Exchange were positive. The process also caused the spread of weeds that soon became invasive pests in the new environment.

The Columbian Exchange in Africa

Considerable scholarship has been dedicated to researching the scope and significance of the Columbian Exchange between the Old World and the New World after 1492. To date, however, much of this research has focused on the impact on the Americas and Eurasia, and relatively little focus has been aimed at the African component of this exchange. This is unfortunate, because what research has been undertaken points to both significant African contributions to the exchange and a significant impact of that exchange in Africa.

African rice appears to have been one of the most significant cultivars introduced from the Old World to the New World. While the vast majority of rice grown in the New World is now of the *Oryza sativa* variety, which comes from Asia, *Oryza glaberrima*, from West Africa, seems to have been the first type cultivated in the Americas. This variety of rice was initially developed in the inland delta of the Niger River and was later grown along the West African coast in the present-day regions of Senegambia, Guinea, Sierra Leone, and Liberia. Whether African rice was introduced to the Americas by enslaved Africans or by Portuguese sailors is still debated, though the weight of evidence seems to suggest that it was the former. Whatever the case, African rice became an important component of the economy first of Brazil and later of the tidal plantation region of the Carolinas in North America. Notably, this element of the Columbian Exchange was not only environmental but also technological, as it was African knowledge of rice cultivation that made rice farming in the Americas a success, since Europeans were initially ignorant of how to grow the crop.

Other crops introduced from Africa include okra, oil palms, coco yams, and water yams. The latter three became particularly important crops in South America. African varieties of pepper, including the Malagueta pepper, were also imported to the Americas. Guinea fowl were also introduced into South America, providing a popular alternative to chickens. In recent years, African millet and teff, a highland grain from Ethiopia, have become popular with whole-food advocates in the Americas.

Crops from the Americas were embraced by Africans across the continent. These included a number of crops that became popular around the world, including tomatoes and potatoes. Three crops in particular, however, would have a particularly significant impact in Africa south of the Sahara: manioc, maize, and peanuts.

Manioc, a root crop native to the Amazon, can grow in low-light forest conditions. Its fruit can grow to considerable size and can be left in the ground until it is needed. It is, however, poisonous in its raw unprocessed state. Once African populations learned to prepare it in a way that removed its poisons, manioc was well suited to providing an excellent source of food energy in the forest regions of West and Central Africa.

Maize, too, was energetically embraced by African populations. In particular, maize's high rate of growth could allow for multiple crops to be raised in a single growing season, particularly in the tropic regions of Africa. Together, manioc and maize helped fuel a food-production revolution that helped human growth rates in the challenging environment of the African forest region. In southern Africa, maize eventually became the staple food crop, and it also found popularity among North African populations as well.

Peanuts, which originated in the Andes region of South America, were introduced into the savannahs of West Africa, where they soon became a staple crop. Roasted as a snack or cooked into stews and sauces, they provided an excellent source of protein for the region's population of sedentary agriculturalists. Peanuts were also enthusiastically embraced in Egypt and parts of southern Africa.

The Columbian Exchange in Africa and the Muslim World

The biological transfer of plants and diseases between the Western Hemisphere, Africa, and the Muslim world reflected the interconnections of Portuguese, Muslim, and other Indian Ocean traders by the beginning of the sixteenth century. Although the impact was likely negligible at first, eventually diets, nutrition, ecology, and lifestyles were profoundly affected by the introduction of new species. The cultivation of New World crops in Africa and Asia contributed to the processes of mercantile imperialism. The spread of African and Muslim commodities promoted new systems of plantation agriculture across the Western Hemisphere.

Competing systems of Portuguese and Muslim commerce met in the Indian Ocean after two key events: the capture of Constantinople in 1453 by the Ottoman Turks and the Portuguese capture of ports in Asia from Goa (1510) to Malacca (1511). While trade circuits changed hands and shifted partners, the list of exchanged items ranged from dreaded disease to desirable spices and intriguing new food crops, with sources continents away. Because of existing Iberian links on the Mediterranean and overland roads out of the reach of Portuguese ports, both continuity and change characterized the era of early global trade.

Known as the Columbian Exchange, the period of early hemispheric connections has typically been perceived as primarily involving temperate zones, especially as focused contacts across the Atlantic world between Europeans and the Americas. Seed transfers have emphasized the role of European agriculturalists. African and Asian participants, when considered, have sometimes been characterized as merely passive recipients of new crops. Recent scholarship has altered this view by adding African and Islamic world contributions to the list of key commodities, including coffee, melegueta pepper, rice, and cotton, whose transfers dramatically changed political economies around the world.

Black rice (*Oryza glaberrima*) was originally domesticated in West Africa by at least 300 CE, the documented date for grains recovered from the archaeological site of Jenne-Jeno on the inland Niger delta. Rice agriculture spread to three distinctive environments of West Africa (tidal floodplains, inland swamps, and uplands), as observed by North African merchants and early European visitors to the Guinea coast. Trade in rice reached offshore islands and thence across the Atlantic. Eventually *O. glaberrima* was grown in Virginia and the Carolinas alongside tobacco and flax. Key to its transplanted success in the Americas was the crop-specific technologies and knowledge systems transferred by enslaved

➤ MAIZE IN EGYPT—A NEW GIFT OF THE NILE

The early sixteenth-century introduction of maize (corn) from Venice to Egypt began a food revolution in Africa. Maize's journey from the Americas followed maritime and overland routes, connecting its Iberian entry point to northern Italy, North Africa, and West Asia via Mediterranean trade routes by the middle sixteenth century. After a successful introduction to the Nile Valley, maize spread to other regions, reaching East Africa via Arab and Banyan merchants and eventually conquering the continent and triggering a carbohydrate revolution.

It is likely that maize approached West Africa from at least two directions. As attested by the root word for the crop in several West African languages, *masa* (after *masar*, meaning Egypt) and

makka (Mecca) implied its arrival as a traded commodity and a souvenir that pilgrims brought home from the Islamic hajj to the holy city. The crop gathered popularity as a boiled or cooked foodstuff, supplanting other crops such as sorghum and millet and complementing rice agriculture. At nearly the same time European merchants brought Caribbean and Brazilian flint maize to coastal ports, where the crop settled into the savanna-forest mosaic horticulture of West Africa by the 1640s and led to population increases in the following two centuries. Ironically, the American crop returned across the Atlantic when African traders and rulers sold their maize crops to European slave ships bound for the Americas.

—Candice Goucher

African women by the 1690s. Captive African farmers and European merchants transported not only rice but also other crops (sesame, guinea corn, and okra) across the Atlantic during the era of the slave trade.

Maize (corn) was one of the most influential of the New World imports moving in the other direction. Early words for the crop in East African languages suggest its origins via coastal trade on dhows. Maize was grown in Portuguese garrisons. The cultivation of maize provided a key food that supported the growth of Arab and African caravan trade to the inland regions, which supplied ivory, slaves, and other goods in return. Eventually maize became a saleable commodity and was used as a staple crop for daily and local beer brewing in many regions of the continent. In West and Central Africa the introduction of maize supported local population increases and provisioned slave ships.

Another important food crop introduced by slave traders was cassava, which was well suited to the requirements of West and Central Africa's forest ecology. Thriving in nutrient-poor soils and less labor-intensive than other forest foods, cassava was especially critical in the changing environment between 1630 and 1860. The crop adapted well to recently cleared forests and supported local state expansion, the caravan trade, and population growth, changing the traditional ecology and practice of fallow cycles.

Not all of the crops introduced from the Americas were foods. Tobacco spread quickly through trade caravans. By 1664 it was observed being grown in great abundance in the Senegambia region of West Africa. By the end of the seventeenth century tobacco and other imports from the Americas had become substitutes for the Indian, Arab, and Persian products in the Indian Ocean trade.

African and Asian pathogens and parasites fought back against the European invaders and slowed settlement. The early Portuguese traders complained about the diseases, fevers, dysentery, and parasites they encountered in the tropics from the 1490s on. Venereal syphilis was exported from the Americas, creating epidemics in Europe in the 1490s and the early sixteenth century. The disease ravished the Azores, Madeira, and Canaries, but the impact on continental

demography seems to have been negligible. The spread of animal-borne diseases would affect a far greater impact in the nineteenth century.

The Columbian Exchange in West Asia

The arrival of Portuguese explorer Vasco da Gama in 1498 inaugurated direct relations between India and Europe, culminating in the gradual imposition of English control over the Indian subcontinent in the eighteenth and nineteenth centuries. By the sixteenth century, a consequence of the contact between Europeans and India as well as more western areas of Asia was the exchange of goods, crops, animals, people, and diseases between the new European colonies in the Americas and Asia. This biological exchange between the Americas and Eurasia (and Africa) was coined the “Columbian Exchange” by historian Alfred Crosby in reference to Christopher Columbus, the Genoese explorer popularly credited with initiating contact between the Western Hemisphere and the Eastern Hemisphere.

Though this contact between previously isolated worlds was sometimes disastrous—due to the introduction of foreign fatal diseases, animals, and plants that could ruin native populations and ecosystems—it was generally beneficial to western and southern Asia. Indigenous Americans were more vulnerable to Asian, European, and African diseases than Africans and Eurasians were to American sicknesses, and though American peoples reaped the benefits of new crops and animals (such as the Plains Indians, who quickly embraced the horse), so did Eurasians and Africans.

➤ MAIZE COMES TO INDIA—A LIMITED HISTORICAL RECORD

Corn, or maize, was brought to India by the Portuguese in the early seventeenth century. Corn originated in Mexico and was brought to Europe along with other New World crops by Spanish explorers in the early sixteenth century. Soon adopted by farmers in Spain, Portugal, Italy, and Morocco, corn was then distributed by land and sea routes as far away as India and China by the end of the seventeenth century.

The importation of corn and other crops into India is not well documented. Abu-I Fazl's *Ain-i Akbari*, the most important source for the politics and economics of the early Mughal empire, provides a detailed description of agriculture in the empire around 1590 but does not include corn in any of its crop lists. Moreover, the Mughals were somewhat indifferent to the Portuguese and recorded little about them in other documents. There are also gaps in the Portuguese records due to the destruction of the archive in Lisbon's India House in the earthquake of 1775.

The evidence suggests that corn was introduced into the Portuguese colony of Goa as early

as 1620. By the 1640s, corn is listed in local revenue records in what is now the Indian state of Rajasthan. Corn is not mentioned much in Indian government records until the nineteenth century, when the British government conducted agricultural surveys of its newly conquered territories. By this time, farmers were replacing certain varieties of millet with corn in areas with relatively dry soils, as corn was more productive and required less labor.

The spread of native American crops allowed areas of Asia and Africa that were previously sparsely populated (due to poor soil or a lack of available foodstuffs compatible with the local climate) to grow exponentially, as diets became more healthy and varied and food was increasingly plentiful. In India, corn and chili peppers, both American crops, quickly became staples. Other domesticated American plants that became widely available in western Asia, often becoming key components of Asian cultures, were tobacco, potatoes, sweet potatoes, peanuts, manioc, cocoa, and beans.

Tobacco was brought into the Ottoman empire at the end of the sixteenth century, and it quickly became an integral part of daily life throughout Islamic lands. Though the potato was not popular in the Fertile Crescent, its relatively high amount of nutrition and its hardiness made it a key crop for the mountainous region stretching from eastern Europe to the Caspian Sea. Sweet potatoes were introduced wherever Portuguese or Spanish trading posts were set up.

Following their introduction, also by the Portuguese and Spanish, peanuts, cocoa, and manioc became widely consumed throughout the Sahel and the Near East. Though certain types of beans were long cultivated in the Near East, several new types were introduced as part of the Columbian Exchange, and they continue to be staples throughout North Africa, the Near East, Turkey, and Afghanistan.

By the seventh century, due to maritime technological advances, trade flourished between the Old World and the New World to the extent that the exchange of goods became essentially global. Spices, tea, saltpeter (used for making gunpowder), and other goods deemed essential were now traded by Europeans and Asians for American products such as tobacco, lumber, gold, and silver.

Irrigation Systems in Early Modern South India

For centuries, Indian farmers have struggled with having either too much water or too little water. Some parts of India receive so much rainfall, unfortunately all at once, that farming is difficult due to flooding, erosion, thick jungle growth, or even changes in soil chemistry. Most of India in fact is arid, mainly receiving intense seasonal rains called monsoons once or twice a year for a few weeks at a time, and briefly yellow and red hues turn to green.

The construction of irrigation works played a role even in the oldest urban civilizations of India, but there were no large-scale irrigation systems until the thirteenth and fourteenth centuries. At that time, Turkish rulers brought irrigation techniques from the Islamic lands of Central Asia to the North Indian plains, while tank irrigation technologies in South India were spread by migrating Telugu-speaking warlords. When the Mughals developed irrigated tracts during the height of their rule over northern India (1526–1707), they mainly resuscitated and enlarged canal systems originally constructed by the rulers of the Delhi sultanate (1206–1526). In South India, the Telugu diaspora resulted in the colonization of irrigated strips in hitherto dry areas situated between major rivers, contributing to the rise and growth of the kingdom of Vijayanagar.

Portuguese and Persian visitors to Vijayanagar (encompassing large parts of South India) in the sixteenth century were astonished by the size and prosperity of the city, which was described as being equal in size to the largest cities of Europe. However, what really astonished these foreign observers was the location; the metropolis was situated on a high hot plateau country of open plains and rocky desiccated mountain ranges. Yet here among

startling enormous boulders visitors found massive temple complexes, sprawling palaces, and perhaps the largest marketplace in the early modern world, multistoried bazaars extending more than half a mile (.8 kilometers) and loaded with produce and merchandise from every part of the known world. Plantain groves, paddy fields, and gardens flourished along stone-lined channels that conducted water within the city walls, which enclosed over 20 square miles (52 square kilometers) of densely populated and developed land. Without the dams and irrigation works constructed along the Tungabhadra River, Vijayanagar could not have existed.

The irrigation system of Vijayanagar was hardly unique to South India. Farmers in the regions had occupied the narrow river valleys early on, and the expansion of agriculture had required the development of ingenious water storage and distribution technologies. Tried and true ancient methods continued to be used in the early modern period. Dams called *bands* (pronounced “bund”) were built across the outlets of natural watersheds to form reservoirs, or *cheruvus*, during the rainy season. Often these lakes were no larger than ponds, with small channels leading to a few acres of irrigated land nearby. In some places, however, the dams held back several square miles of water to a depth of 30 or 40 feet (9 to 12 meters). A cheruvu like this could irrigate miles of crops and fed a complicated system of canals, subcanals, and local channels. Cheruvus, or tanks, are still an important part of the South Indian environment, and they can be seen from the air, forming large and small fan-shaped patterns of water or alluvial dust, depending on the season, at intervals of 3 or 4 miles (4.8 to 6.4 kilometers), each with a string of fields and villages trailing downstream from its dam.

The Chola rulers of medieval Tamil Nadu had built enormous dams, tapping the waters of the Kauveri River to irrigate vast swaths of land for rice and other crops. Ruins of the massive anicuts, or diversion dams, constructed by the Cholas can still be found along the Kauveri between Trichinopoly and Thanjavur. By the early modern period many of these works had fallen into ruins, but some remained, albeit on a smaller scale. The prosperity of the Thanjavur country in the eighteenth century was due

► IRRIGATION FOR AN ARTIFICIAL PARADISE IN NORTH INDIA

Irrigation had less to do with agriculture in northern India than in South India, partly because the Yamuna-Ganga Plains were well watered by large rivers fed by the melting snows of the Himalayas. Only in eastern Punjab and Haryana did the Mughals build major irrigation works. In most parts of North India, the construction of canals merely led to waterlogging, and the seasonal flooding of low-lying areas remained a major problem in the Punjab until the late nineteenth century. Peasants who needed water during the dry season made use of wells or Persian waterwheels or else built small-scale local irrigation systems. The Mughal conquerors, however, loved running water. Splashing fountains reminded Babur of the rivers of mountainous Ferghana, and the stagnant waters of the North Indian plains depressed him. He and his successors therefore committed themselves to laying out royal gardens all over their expanding empire. Each garden foreshadowed the joys of the Islamic paradise, especially the promise of flowing clear water. Mughal palaces boasted, among other

wonders, channels carved into the marble floors and filled with rosewater to both cool and scent the air. Because of their Central Asian heritage, the Mughals were familiar with *qanats*, or underground tunnels and cisterns, used to collect runoff and groundwater in arid hilly country and transport it for miles to low-lying arable land, where it could be used to irrigate farmland and gardens. All Mughal building projects were paired with ambitious irrigation systems, with flowing water a crucial design element. The Mughals rarely made mistakes, but one of the biggest was Akbar's decision to build a beautiful sandstone palace-city at Fatehpur Sikri, southwest of Agra, a site that never became the ideal capital it was meant to be because there was not enough water to support a large population. It is hardly surprising that Shah Jahan, seeking a new capital, selected Delhi, laying out his new city alongside the Yamuna River, the waters of which were diverted to irrigate extensive royal gardens.

—James Hoover Frey

to the anicut at Trichinopoly. This large stone dam divided the Kauveri into the several channels that formed the rich deltaic lowlands of the kingdom of Thanjavur. With a perennial supply of water, the Thanjavur lowlands produced three crops of rice a year. Rice was cheap there and thus so was labor, and this was one of the reasons why weavers flocked to the kingdom's villages, in turn attracting European traders to the coast, where several foreign factories, or trading outposts, flew the flags of the competing East India companies. During the Carnatic Wars, fought for control of the Tamil Country in the mid-eighteenth century, it was not surprising that Trichinopoly was the sought-after prize. To control the city was to control its anicut and the water supply of Thanjavur, upon which much of the regional economy depended. The East India Company's ability to build a territorial empire in South India was due at least to some extent to its successful seizure and defense of Trichinopoly.

In South India, the maintenance of irrigation works was the responsibility of the king.

The *nayakas* and the Muslim *nawabs* who took over the Carnatic during the eighteenth century followed the administrative pattern set by the Cholas, assigning the revenue of whole villages to pay for the maintenance of dams and canals. Local officials were appointed to collect and administer these funds and oversee any necessary work. Village officials regulated the irrigation system, and farmers who received water contributed to the upkeep of their local reservoir. Usually, canal floodgates were opened at a farmer's field for a specified amount of time, thus rationing the flow of water. Wherever channels extended across the lands of several villages or from one district into another, a fair degree of political cohesion was required in order to keep villages upstream from taking more than their fair share of water. Needless to say, the slightest disruption of the political system plunged irrigation works into chaos, and the cutting of canals and channels by the inhabitants of rival villages was a common occurrence. It is not surprising that one of the East India Company's first and most urgent tasks upon assuming political

control in India was taking over the management of irrigation works.

Digging Salt Earth— The Subtropical Environment and Saltpeter Production in Early Modern India

Saltpeter is a common name for potassium nitrate, a mineral compound vital for gunpowder production. Gunpowder was traditionally produced through mixing sulfur, charcoal, and potassium nitrate (saltpeter). Saltpeter is a naturally occurring compound, often extracted as a by-product of bird and bat droppings. However, it is relatively rare in its most basic and easy-to-obtain form found on the ground in certain climate zones in America, Egypt, and India.

The use of gunpowder was widespread in seventeenth-century India. It is unclear exactly when gunpowder was first used in India or how the invention arrived there, but it was certainly available by the fourteenth century. It is possible that the Mongols brought gunpowder from China or that it arrived directly from China through missionaries and traders. In any case, India became one of the world's leaders in gunpowder production and, by extension, gun making by the sixteenth century. One of the reasons why India was on the cutting edge of firearms manufacture was its relatively plentiful supply of native saltpeter.

In early modern India saltpeter was commonly found in the Ganges River valley, one of the few places on earth where the soil is saltpeter-rich. As historian Asitesh Bhattacharya

INDIA SALTPETER—KEY TO EUROPE'S “MILITARY REVOLUTION”

Europe's religious wars of the sixteenth and seventeenth centuries required a vast supply of gunpowder. At first, saltpeter, one of the key ingredients in gunpowder, was extracted from bird and bat droppings. To increase its availability, European saltpeter procurers (or saltpetermen) would scour dovecotes for dove droppings, much to the consternation of bird lovers, as the birds and their eggs were often destroyed in the process. Birds and bats were also raised specifically for the saltpeter produced from their droppings. Even so, it was difficult to gather saltpeter in quantities large enough to mass-produce gunpowder, and by the early 1600s European gunpowder manufacturers were growing desperate, as the increasingly large European armies, bolstered by thousands of conscripts (who could be relatively easily trained in the use of firearms), consumed vast supplies of gunpowder. The answer to the European saltpeter shortage was soon found in India.

India was one of the few places in the world where saltpeter was found in large quantities in its natural state. India saltpeter, gathered primarily from the Ganges River valley and exported from western India, was of a particularly high quality (and cheap) and thus was much prized by European traders. The British and Dutch East India companies, in particular, were well known for their saltpeter trading.

As European states were constantly at war with one another during the sixteenth to eighteenth centuries, the need for larger armies and modern bureaucracies to finance and control them quickly became apparent. Because it was difficult to effectively train large amounts of raw recruits in anything but firearm usage, European military tactics soon evolved to reflect the shift from close combat to ranged warfare with handguns and artillery (and, in response, larger fortifications). This shift in European warfare is commonly termed Europe's “Military Revolution” by historians. However, without the mass influx of India saltpeter, Europe would not have had enough gunpowder to support its increasingly large armies, and no such “revolution” would have been possible. As a result, Europe's military, technological, and economic dominance of the world from the seventeenth to the twentieth centuries would have been delayed or perhaps even prevented.

—Matthew DeFraga

points out, the “earth of the Gangetic India is richly impregnated with saltpetre in a natural state, which can be extracted by lixiviation, evaporation and crystallisation without the aid of fire,” making its gathering relatively safe. The subtropical environment of Bengal was ideally suited to the natural occurrence of saltpeter, as it coalesced on the ground immediately after the monsoon season. Digging through the soil produced large chunks of saltpeter that had filtered through the earth and bonded together. Though Europe was a leading consumer of gunpowder, particularly during its many religious wars of the sixteenth and seventeenth centuries, it lacked the ideal climate for saltpeter production, and the European demand for saltpeter soon exhausted Europe’s native supply. By the early seventeenth century, European traders were forced to turn to subtropical India for saltpeter.

The Columbian Exchange in East Asia

The transcontinental biological exchanges ignited by Christopher Columbus’s initial encounter with the Americas in 1492 had a significant effect on foods available to East Asians. Specifically, the transfers introduced several crop varieties into East Asia that thereby encouraged the cultivation of new staples and drastically altered dietary habits. Through the sixteenth and seventeenth centuries, both China and Japan benefited from the adoption of a vast array of new crops from the Americas. East Asian agriculturalists eagerly adopted staple crops such as potatoes,

peanuts, and chilies, which allowed for the expansion of their respective populations. Crops such as the humble potato and peanuts allowed formerly nonarable land to be brought into cultivation, thus ensuring ample food supplies for burgeoning populations and lowering the incidence of famine. East Asian regional culinary styles and dishes changed as palates were exposed to interesting and appealing new flavors and spices.

After 1500, the diffusion of American crops to the Far East was facilitated first by the prevalence of Portuguese trade networks along the Indian Ocean and Southeast Asia. These networks had commercial ties to Spanish merchants in Iberia, who in turn had access to crops from the Americas. After the Spanish conquest of the Philippines in Southeast Asia in 1565, Spain established Manila as a major trade center, directly linking American products to Chinese merchant networks. Both the Spanish and the Portuguese introduced American crops to the Far East through these trading posts, situated conveniently amid the greater East Asian commercial networks. Chinese and, to a lesser degree, Japanese merchants eagerly traded their products with Iberian traders for these new food staples.

Before the introduction of American crops, Ming China relied on the intensive cultivation of rice to ensure the food supply of its burgeoning population. This ensured heavy population density along the lowlands of southern China, where the rice crop thrived and left much of the northern regions barren and uncultivated. During the late Ming dynasty and early Qing dynasty, American maize, along with peanuts and potatoes, allowed Chinese peasants to cultivate these barren highlands. These new crops allowed previously undeveloped land to be brought into cultivation and led to an increase in overall crop yields for the entire country, in addition to the already extensive rice yields to the south. Manioc from Brazil also entered China and Japan and became part of a more diverse diet.

Much like China, Japan had also relied on intensive rice cultivation to feed its population. Initially, potatoes were introduced in Japan by Russian merchants in the late 1600s. Japan also benefited from the introduction of American crops, but they were less popular until episodes

➤ MAIZE, PEANUTS, AND MANIOC

Maize, peanuts, and manioc, which were staples for the indigenous peoples of the Americas for centuries, entered the Eastern Hemisphere in the sixteenth and seventeenth centuries and allowed previously marginal lands in certain climates to be brought into cultivation. Typically cereals and grains, such as wheat, barley, and rice, were grown through much of Eurasia as main staples for subsistence. As these were limited to certain regions, climates, and growing seasons, the incidence of famine was increasingly high due to drought, a harsh winter, or widespread warfare that frequently disrupted distribution networks. However, after 1500 the introduction of New World

crops, particularly maize, peanuts, and manioc that would grow in what were deemed nonarable marginal land and inhospitable climatic conditions, allowed for a massive expansion of the foods available in the Eastern Hemisphere. Maize fed both livestock and the destitute, given its high yields. Peanuts thrived in hard marginal land, previously unsuited for much else. Manioc grew in tropical and subtropical regions, where not much else would provide a viable staple crop. From Europe to sub-Saharan Africa and to the reaches of East Asia, these crops provided a vast new supply of food for all the peoples of Eurasia.

—Abraham O. Mendoza

of famine forced a starving populace to appreciate the nourishment offered by potatoes and maize. Like early modern Europe, sporadic famines forced East Asian populations to adopt American crops previously seen as suspect or associated primarily with food of the poor. Some historians suggest that this expansion of the food supply is a considerable factor in the rapid growth of East Asian populations in the sixteenth and seventeenth centuries.

Regional cuisines in both early modern China and Japan were radically altered by the introduction of American crops. The infusion of red peppers, capsicums, peanuts, maize, manioc, and potatoes into Chinese culinary habits across various regions changed local food habits. Peanut oil, extracted from peanuts, became a pivotal part of Chinese food preparation, particularly in frying. As the Chinese were used to spicy foods due to their long-standing procurement of spices from Southeast Asia, American spices (specifically in the varieties of peppers) also became a regular condiment in many regional Chinese dishes. However, Japanese dishes were not noticeably affected by the infusion of American foods, outside of some isolated regions that depended on either maize or potatoes for subsistence. Fish and rice dishes remained the food of choice for most of the Japanese populace unless faced with dire economic situations. Nonetheless, both China and Japan adopted New World crops gradually over several centuries and

were but one example of the global sweep of the Columbian Exchange.

The Columbian Exchange in Europe

The influx of novel foodstuffs from the New World to Europe took several centuries to have an impact on Old World agriculture and foodways and varied regionally. Initially, many foods from the New World were seen as repulsive, fit only for livestock or the lowly peasant, and were generally resisted by Europeans. However, due to endemic famines (which were common in this period) as a consequence of widespread bad harvests and climatic conditions between the fifteenth and sixteenth centuries, many Europeans began to consume New World produce, particularly beans, maize, and potatoes that were more resistant to disease and could be grown on less land far more productively. In addition, New World crops allowed the lower strata of European

► THE POTATO COMES TO IRELAND

The Irish are famous for their association with the humble potato, stemming back to the initial reception of the New World crop in the Emerald Isle. The potato was introduced in Ireland late in the sixteenth century, and within a century Ireland was already known for its proclivity for the tuber. The deep cold soils and cool climate of Ireland are ideal for potato cultivation. Under the exploitative and oppressive rule of the English, many Irish were condemned to live in dire poverty and deprivation. The potato allowed Irish peasants to sustain themselves on the small tracts of English land that made up the bulk of Ireland. On a mere acre (.4 hectares) of land, a typical Irish peasant could grow enough food to sustain a small family for approximately a year. The inclusion of potatoes in the Irish diet led to better health and a substantial growth in the overall population. It is estimated that the average Irish male consumed solely 10 pounds (4.5 kilograms) of potatoes a day for sustenance. However, with the coming of the potato blight and the resultant Irish Potato Famine in the 1840s, this overreliance on one crop ultimately proved to be catastrophic.

—*Abraham O. Mendoza*

society to cultivate and harvest life-sustaining crops on small plots of land, thereby increasing the life expectancy of the average person.

Beans were one New World food that initially did not find acceptance in Europe. Scholars believe that beans were first cultivated in Europe in the sixteenth century and only became widespread by the eighteenth century. Europeans took a long time acquiring a taste for beans, possibly because Europe entered a long period of cold weather in the mid-sixteenth century that lasted well into the eighteenth century, which did not allow for adequate growth of the crop. More important was the European perception of the bean as food fit only for lowly Indians and of little nourishment for themselves. However, over time Europeans developed a fondness for beans in their many varieties, in part because it thrived in regions with only a few months of hot weather, allowing farmers in the cooler latitudes to grow them successfully.

Maize, otherwise known as corn, also made little headway in early modern Europe and was not regarded as fit for human consumption. It was grown in various regions throughout Europe from the early sixteenth century as fodder for livestock but grew in importance in the latter half of the seventeenth century as a viable food source for people. It emerged as part of the French diet, which leads some historians to stipulate that it might help explain the population growth of that country in the late seventeenth century, particularly in rural areas. Maize became the staple of choice in much of southern Europe (Spain, Italy, and Portugal), particularly for the peasantry. Polenta, a cornmeal derivative of maize, became a staple dish for Italians. The widespread usage of maize in these regions is credited with contributing to a steady growth of population in the eighteenth century, helping these areas recover from earlier population decline. Taking up less land to grow and being resistant to extreme heat and cold made this humble crop less susceptible to climatic extremes that otherwise would typically lead to famine.

Potatoes also contributed substantially to European demographic expansion, as had beans and maize. From the outset, they were seen as exotic products and even as aphrodisiacs but not as a source of sustenance. In the sixteenth century, potatoes even were blamed for being a source of leprosy. They were also typically perceived as a food fit only for the lower social orders. However, over time, potatoes offered peasants and laborers a cheap and especially easily cultivated crop for human consumption. European farmers learned to grow potatoes on small plots of land and found them resistant to extreme cold, providing nourishment for peasants in dire need. It became a major staple in Ireland and Germany, contributing to the population growth and improved health of the peasantry.

Other crops, such as tomatoes and peppers, made little headway in Europe during the fifteenth and sixteenth centuries. Their impact would be felt much later, particularly in the southern European nations of Italy and Spain, where they are prevalent in the diet and recipes of those regions. While the Columbia Exchange did introduce these crops into Europe, they did not have the same level of impact as beans,

maize, and potatoes, which were resilient in the extreme climatic conditions of the Little Ice Age that could lead to large regional famines. While famines continued well into the eighteenth century, the growing prevalence of New World crops allowed some regions to survive and even experience substantial population growth.

The Age of Buckwheat—Climate, Food, and Famine in Early Modern Europe

The relationship among climate, food (in the form of buckwheat), and famine characterized much of early modern Europe. Global climatic fluctuations known as the Little Ice Age (1500–1850) contributed to the frequency of bad harvests in early modern Europe, resulting in widespread famines throughout various regions. Overreliance on wheat, vulnerable to cold weather, as a staple crop resulted in the reoccurrence of famine for much of the European population. As the European economy shifted from subsistence farming to commercial farming, with larger yields and surpluses, and also began to include more New World crops (maize, beans, and potatoes) as staples for mass consumption, the frequency of widespread famines lessened by the end of the eighteenth century.

Famines occurred throughout much of this period locally, nationally, or occasionally across all of Europe. In particular, England suffered a series of food shortages during 1527–1528 (the “Great Hunger” of 1527 was responsible for the deaths of 10 percent of the English population), 1550–1552, 1557–1559, 1596–1598, and 1623–1624. Records show that in France, Paris alone suffered famines during 1520–1521, 1523, 1528–1534, 1548, 1556, 1560, 1565, 1572–1573, 1574, 1587, 1590, 1595–1598, 1621, 1625, 1629, and

1631–1632. Similarly to England, some of these famines lasted several years.

Climatic conditions, considerable population growth, the overreliance on subsistence farming, and the price revolution (1470–1650) contributed to the constant outbreak of famines in early modern Europe. The long-term cooling of the Little Ice Age had a significant effect on food production by decreasing the elevation at which crops could be grown. The gradual change in climate also decreased the land available for cultivation, thereby decreasing staple crop outputs, particularly for wheat. Steady population growth, which occurred during periods of good harvests, would deplete the grain supply available, making the mass of the populace vulnerable to famine. Much of the wheat crop was grown on small parcels of land by peasant proprietors or renters, who gained only enough to subsist on, while much of the grain, grown for commercial purposes, was exported to other regions for the profit of the major landowners. In times of famine the grain prices would go up as a consequence of the price revolution. The scarcity of grain allowed wheat speculators to increase the market price of wheat to ensure a sizable profit in times of dearth. Higher wheat prices affected those least able to afford food, resulting in widespread death among the lower strata of early modern European society.

Other factors that contributed to the outbreak of famine were endemic warfare, lack of government involvement, and the rapid depletion of food surpluses in urban areas to the detriment of the rural population. Many artificial famines were a result of the effects of warfare on civilian populations, in particular the Thirty Years’ War (1618–1648) during which marauding armies of mercenaries confiscated, consumed, and prevented the efficient transport of food to towns and cities. Local and regional governments were slow to respond to the famine. Although local governments often maintained surpluses, few held sufficient stocks for the ever-growing populations. On the outset of a famine, rural populations necessarily resorted to eating the seeds for the next year’s crop, triggering conditions for a future famine. As a famine continued, many peasants sought refuge in the nearest regional town or city. Yet here townspeople

horded their limited grain supplies, and many of the rural exiles starved.

Over time, new forces eased the incidence of widespread famine. One change was gradual inclusion of New World staple crops, which were less vulnerable to colder climatic conditions. Another was the shift from subsistence to commercial agriculture, which brought greater crop yields. As Europeans realized that maize (corn), beans, and potatoes could be cultivated in cold conditions, they slowly developed a taste for these American staples. Commercial agriculture put land into more productive usage, slowly ending the dominance of subsistence agriculture and the stranglehold of large aristocratic proprietors over much of the land. Greater variety and higher yields of wheat led to surpluses and lessened the chances for famines. However, famines recurred throughout much of Europe well into the eighteenth and nineteenth centuries but were due more to human agency than to the effects of climatic conditions.

Changes in the Land—Human Alterations in the Environment of British North America

All human groups change their environments, as historian William Cronon notes, and European settlers in British North America were no exception. From 1600 to 1800 the environment was dramatically transformed in British North America. The first successful English colony was established at Jamestown, Virginia, in 1607. Thirteen years later, settlers arrived in New England. Europeans, though, did not arrive alone. They brought with them disease, livestock, and vegetation. Together, these organisms revolutionized the North

American ecosystem by altering human and animal demographics and land use and by introducing numerous animal and plant species.

Changing population patterns were central to British North America's ecological transformations. The indigenous Indian populations of British North America were decimated by Eurasian diseases such as smallpox, influenza, plague, malaria, yellow fever, and tuberculosis. These diseases often developed into virgin soil epidemics, or new and deadly diseases that spread to nearly all members of a population. In the first 75 years of settlement in New England, the Native American population dropped from more than 70,000 to less than 12,000. American Indians had previously been isolated from Europe and its diseases. Moreover, Native Americans' pathogens were less developed and deadly in comparison to those of the European settlers. Therefore, when Native Americans came into contact with European settlers, their immune systems were defenseless. In contrast, the settler population grew rapidly. By the 1750s approximately 1 million Europeans lived in North America.

European settlers imported an economic system that combined late medieval manorialism with early modern capitalism. Prior to European settlement, Indian groups had utilized the environment in various ways. For instance, in southern New England, Native Americans farmed the land in addition to hunting and gathering. As part of this process, they moved homes every few months and fields after a few years. As the American Indians declined, the European economic system took over. Native Americans in southern New England lost most of their lands due to disease and sale. By the eighteenth century this area was dominated by European farmers, who settled on permanent plots that were divided by fences and raised domesticated animals.

Animal populations in British North America changed significantly from 1600 to 1800. European settlers brought animals unknown to the American continents, including horses, cattle, pigs, goats, sheep, chickens, cats, rats, and rabbits. European settlement also led to shifts in animal habitats. In 1600 deer, wolves, bears, turkeys, and beavers were all common in southern New England. Two hundred years later, the

► CREATIVE DESTRUCTION—SUGARCANE IN THE CARIBBEAN

Sugarcane was first introduced into the Caribbean in 1493, when Columbus visited Hispaniola. The Spanish replicated these sugar ventures, but they encountered technological obstacles and then labor issues as the local Arawak Indians died off. By the end of the century they had abandoned Caribbean sugarcane production. In the seventeenth century, though, the English and French revived the venture. They initially used their Caribbean colonies for settlement. The Caribbean sugar revolution did not begin until the 1640s, when French and English Caribbean colonies began producing sugarcane and importing African slaves. West Africans were a particularly attractive labor pool because they had been exposed both to Eurasian diseases and to tropical diseases such as yellow fever and malaria, which were common in the Caribbean. As a result,

newly arrived Europeans were four times more likely to die than their African slaves.

Throughout the seventeenth and eighteenth centuries the Caribbean became increasingly dominated by sugarcane, and food had to be imported. For instance, 80 percent of the land in Barbados was used for sugar production in 1767. Together, European settlement and sugarcane production revolutionized the Caribbean's demographics. For example, in the French colony of Saint Dominigue, 82 percent of its population was slave, 8 percent European, and 10 percent free (primarily of mixed African and European ancestry) in 1740. In the eighteenth-century Caribbean, Native Americans were nearly eliminated and replaced by Africans as the dominant group.

—Kassi Klinefelter

joint efforts of Native Americans and European colonists left this area devoid of nearly all these animals. Moose shared a similar fate. The hunting of moose with the Western musket resulted in their decimation in eastern Canada within 50 years of European settlement. As wild animal populations declined, Western domesticated animals filled the void.

The introduction of domesticated animals contributed to alterations in vegetation and soil erosion. Throughout the early 1600s Europeans imported domesticated grazing animals such as horses, sheep, swine, and cattle. Prior to European colonization, the dog had been the only domesticated animal in North America. North American grasses, with the exception of the gama grass and buffalo grass of the Great Plains, were unable to withstand heavy grazing. Grazing animals destroyed native eastern grasses, which were replaced by European varieties. In particular, Kentucky crabgrass, a combination of English grass and white clover, became a common British North American grass. It spread throughout the 13 colonies and along Canada's St. Lawrence River. Grazing animals also contributed to erosion. They compacted the soil, reducing its oxygen and curtailing the growth of tall plants, which prevented the ground from absorbing water and nutrients.

Thatch-roofed cabins line the single street of Plymouth Colony in 1622. Ill-prepared for fishing and not yet adept at cultivating corn, the Pilgrims struggled to survive for the first years of the colony. (Library of Congress)

The soil was also impacted by regional deforestation. When the first settlers arrived in New England, oaks, hickories, chestnuts, cedars, and pines were common. Trees near North American settlements were cut for firewood, fences, and houses as well as to sell and make room for fields. For example, the white pine that grew to more than 100 feet (30 meters) in height was used for ship masts. The widespread cutting of trees near settled areas created regional deforestation. In New England this deforestation warmed and dried the soil, making it hotter in

the summer and colder in the winter. Drying soil made the ground less able to absorb water, leading to increased floods and forest fires in addition to lowered water tables.

Thus, the British North American colonies were transformed by settlers and their plants, animals, and diseases. As the environment adapted to European livestock, vegetation, or people, increasingly it became more suitable for other organisms. Through this process, British North America was Europeanized from 1600 to 1800, although, as Alfred Crosby states, humans “were seldom masters of the biological changes” they triggered. North American settlers did not control the changing environment, but they did benefit from it.

—Kassi Klinefelter

Horse Cultures—European Influences on America’s Pampas

Covering nearly half of Argentina, all of Uruguay, and the south of the Brazilian state of Rio Grande do Sul, the Pampas are to southern South America what the Great Plains and the prairies are to North America. A region of rolling grasslands dotted by solitary *ombu* tress and crossed by meandering streams and two major rivers, the Paraná and the Uruguay, the Pampas offers ideal conditions for farming and livestock raising. Both activities have dominated the region’s recent history, although until the nineteenth century the Pampas hosted primarily feral herds of cattle and horses that were legacies of sixteenth-century Spanish settlement.

This was not the first appearance of the horse in the Americas. Today’s horse (*Equus caballus*) originated in the Western Hemisphere as

the rodent-sized *Eobippus*, which eventually migrated to other regions of the globe. For uncertain reasons, equids disappeared from the Americas some 8,000 to 10,000 years ago, but their distant descendants returned on Christopher Columbus’s second voyage in 1493. The first horses to live in the Pampas were animals that fled rudimentary Spanish settlements, particularly the first ill-fated Buenos Aires colony of the 1530s. These horses thrived on the extensive grasslands with few natural predators, and as more came with expeditions from Chile, Peru, and Paraguay, they were reported to number in the tens of thousands by the middle of the following century.

In the early colonial period, these horses were scarce. Those that were available were prized for their utility in war and for their role in ensuring land grants, especially for cattle ranching. As these animals adapted easily to the natural conditions of the Pampas, they were also a major technological introduction for Pampas Native Americans. These seminomadic peoples adopted the feral horses (*cimarrones* or *baguales*) as food sources and mounts. This enabled them to become powerful warrior-hunter societies, and they soon exerted control over other natives and resisted European expansion along the frontier of Spain’s American empire until the mid-nineteenth century. They incorporated the horse into their rituals, including horse sacrifices, while indigenous leather-covered three-stone *bolas* used for hunting rhea (American ostrich), wild horses, and cattle were adopted by the local mestizo cowboy, the *gaucho*. The horse played a similar role in some neighboring aboriginal societies in Paraguay and Brazil.

In the mid-seventeenth century the colonial mining economy of Peru and sugar production on the Brazilian coast stimulated the breeding of mules at Salta in northern Argentina and the Brazilian region of São Paulo. Annual mule fairs often transacted between 60,000 and 100,000 animals at a time. The horses used in these breeding programs were descendants of the original importations. At the same time, by the eighteenth century the horse of the Pampas had adapted to local conditions and essentially was a separate breed, the *criollo* (“creole”).

As Spanish settlement expanded over the late colonial period (ca. 1750s to 1810s) cattle

THE CRIOLLO—ADAPTATIONS OF IBERIAN HORSES TO THE AMERICAS

Though mostly a curiosity today, the *criollo* horse breed exists in small numbers throughout the Americas. The first horses brought to the Americas by the Spaniards were of “Berber” stock from southern Iberia, but after their introduction they took on particular characteristics that reflected the ecological conditions in which they thrived. Known widely as *criollo* in Spanish America, in Anglo America they were called *mustang*, from the Mexican *mesteño*, while in Brazil the name depended on the region: *mangalarga* in São Paulo and *pantaneiro* in Mato Grosso. There were only minor physical differences between these animals. They were not as large as most horses today, most standing 13 or 14 hands (under 5 feet or 1.5 meters) at the shoulder and weighing between 700 and 1,000 pounds (300–450 kilograms) while ranging in color from bay to chestnut. With time they tended to become slightly smaller although with increased stamina and agility due to their

adaptation to varied climates and environments. Those that inhabited swampy environments developed wider hooves; others in more wooded regions stood a little smaller than their relatives. The *pantaneiro* was a good swimmer, since over centuries it experienced the annual flooding of the Pantanal floodplain in Matto Grosso. Until the nineteenth century, Pampas animals were pastured free of corrals because wood was scarce and expensive, but feral *criollos* gained a reputation for attracting domesticated horses to their troops by approaching herds and audibly encouraging them to join. Their demise in the early nineteenth century came in large part through the use of firearms by ranchers to protect herds and pastures. By the twentieth century the *criollos* were on the verge of extinction, and societies were formed in various nations to protect and breed the remaining descendants of the colonial *criollo*.

—Robert W. Wilcox

ranching became more common in the Pampas. Horse raising was an integral part of the business, as *criollo* horses were used to herd and capture cattle. Beef cattle appeared at the same time as the horse and, like equids, became feral quickly, developing a reputation for ferociousness in the face of hunting by native peoples. Not as large as their corpulent descendants of today, these wide-horned animals were the Pampas equivalent of the famous Texas longhorn, weighing between 900 and 1,500 pounds (400–700 kilograms) and usually grazing freely on the plain. Early colonial settlers developed a cattle economy that involved hunting the animals on horseback for hides and tallow to be sold in Europe and the silver mines of Peru, not for the meat, which often was left for scavengers. The most important worker in this scenario was the *gaucho*.

Gauchos were the quintessential cowboys who virtually lived in the saddle. Sometimes sporting silver bits and spurs, they commonly rode barefoot with a toe-ring stirrup. They embodied a culture that was romanticized for its free spirit and wild character. Such freedom ended for humans and animals after independent nations were forged in the region in the

Guarani crossing a river in Paraguay, from the book of Father Florian Baucke, describing his missionary journeys in Latin America between 1748–1769. (Photo12/The Image Works)

1820s and the economy began to serve wider European demand for cattle products. As a result, the Pampas *criollo* horse was gradually absorbed into European and Middle Eastern importations to produce a larger and tamer breed. Native peoples, the *criollo*, and the original culture of

the gaucho all but disappeared, although ironically gauchos have become proud identifiers for Argentines today. As the gaucho became a wage laborer, his image was appropriated by Pampas cattle ranchers and horse breeders who dressed in gaucho clothing and frequently defined social status by the competitive quality and equine beauty of the thoroughbred horses they raised.

Effects of European Agriculture on the American Environment

Early European colonists in the Americas attempted to farm the land following the traditional methods of their ancestors. However, the American landscape was not like that of Europe. Staple crops depleted the soil, and nonnative plants and animals disturbed fragile ecological balances.

The forest was quickly cleared for both lumber and agriculture. In order for crops to grow, all trees had to be removed. The most efficient way to clear the forest was through burning, which prevented regrowth of sprouts. Species such as white pine, hemlock, and white cedar did not grow back after clearing. When trees were cleared, this often allowed the seed release of pin cherry and red cedar, dormant species that thrive under full sunlight conditions.

Plowing also changed the land. By turning over soil much deeper than plowing by hand, the process damaged native species in favor of a new habitat with domesticated plants. Plowed soil lost nutrients more quickly than nonplowed soil because more soil was coming into contact with air and water. Plowing was extremely popular, however, because it allowed a farmer to plant more than seven times what he could plant by hand.

One of the greatest agents of change to the environment was European farmers' use of livestock. Pigs, cows, horses, and sheep were integral to European agriculture as resources for food, transportation, wool, and plowing. Farmers were constantly extending the boundaries of their land to accommodate quickly reproducing herd sizes and their food resources, which in turn required more forest clearing. They also caused massive depopulation of native wolves that preyed upon grazing livestock and covered the land with roads to transport their animals to and from regional markets. The native grasses were not adapted for heavy wear and grazing and often died out, being replaced by hardier European species that were brought to the Americas through animal dung. European grass species, such as bluegrass and white clover, quickly covered grazing pastures and replaced native species. Hardy European weeds also flourished, and American ragweed populations exploded.

Likewise, as Europeans burned forest for pasture, they also burned undergrowth, which often changed entire habitats. When tree species were injured by burning of undergrowth, thorny bush species, which were difficult to remove and which cattle could not eat, often flourished in the newly cleared pastures. Much of the new pasture often lay to waste, taken over by stubborn bushes. In addition, because animals were usually fenced into a relatively small area of land, their weight compacted and hardened the soil, squeezing out existing oxygen, which lowered the nutrient value of the land. This often prohibited the growth of plants needed to feed the animals and caused food shortages before the season ended.

Around one year after forest land was cleared, minerals and organic soil matter washed away by rain because there were no plants to

anchor them to the soil. These elements ended up in streambeds, and without plants and rich soil to soak up rain, streams and rivers filled to flooding five times faster than before the Europeans arrived in America. Soil nutrient loss was also hastened by Europeans' habit of farming one species in a field; corn was grown without another crop, such as beans, to provide contrasting nutrients. Also, grazing animals were allowed to clean the fields of corn husks and other organic plant matter. Crop rotation was not usually practiced, and as a field became less and less nutrient-rich, fewer crops grew, and eventually the land was given up for pasture. This, however, inhibited soil-quality restoration because new grasses and tree sprouts were consumed, and the soil remained barren. As crops failed them because of soil failure, farmers became more dependent on livestock for their economic stability.

Hay harvest was completed in late fall, and fields were left empty throughout winters, also causing a chance for significant erosion to occur. The use of fish as fertilizer also hurt soil quality because it brought significant sources of oil into the composition. Fish fertilizer became a valuable enterprise to the colonists and caused great depopulation of native fish species.

In this period, Western contact inaugurated the beginnings of a great environmental transformation as parts of the Americas became a mixture of invasive European flora and fauna in an indigenous habitat. These once exotic plants and animals thrived in their new niches and became the common agricultural plants and livestock of the twenty-first century, causing great change to forest, water, and soil composition.

THE PEACH—A EUROPEAN WEED?

When Europeans arrived in what was soon to be called Georgia, they found peach trees growing in both wilderness and Native American orchards. Native Americans thought them a native species, and they dried the fruit for their winter diets. Colonists found several varieties of peach used by the Native Americans, many more than those peaches found in Europe. These trees reproduce very easily, and Native Americans and European settlers had to weed their orchards regularly to maintain agricultural control over their fields. The settlers and Native Americans of Georgia would have been surprised to learn that peaches were actually brought from Europe and invaded North America a century before. The French explorers brought peaches with them to Florida in the 1500s, and these quickly sprouted trees and spread north, faster than the Europeans could follow. The Native Americans in Florida helped to spread the fruit northward to neighboring tribes, and peach tree populations exploded once the species started growing in the wilderness. By the time settlers reached Georgia, the peach had already established itself and made eastern North America its new home. The Europeans were probably comforted by this familiar taste of home.

Emergence of Horse Culture on America's Great Plains

In modern popular culture, the images of Native Americans and horses are so inextricably mixed that few people realize that the horse was a latecomer to the Plains culture. The impact of horses on Native American peoples was incredibly powerful and changed many things about their culture. Concepts such as property and measures of one's status and wealth were

THE HORSE COMES TO THE DAKOTA

The Dakota, or Sioux, became the archetypical horse culture on the American plains. Before horses came, the Dakota had been a sedentary people from the eastern woodlands. They lived in villages from Minnesota to the upper Missouri River. Their sustenance came from the maize, beans, and squash that they grew along with fruits, nuts, and wild plants that they gathered. Hunters on foot supplemented the agricultural diet with occasional bison meat. Women played an important role in the society since they owned the fields. Society changed when horses began to be obtained by trade and through raids with other tribes. In 1768 Jonathan Carver traveled through the region and noted that the Dakota had no horses. Within two years, however, they had enough horses to begin shifting to a nomadic lifestyle. About eight to ten horses were necessary for each family to move all their possessions, including tepees. Tribal groups followed the movements of the bison herds. By the 1830s the Dakota had displaced tribes such as the Blackfeet from the

Photograph by Edward Curtis of a Sioux war party, about 1900. (Library of Congress)

most desirable grazing grounds and forced them to the west. The Dakota were among the most accomplished equestrians in North America during the nineteenth century, a feat accomplished within only a few decades.

—Timothy J. Watts

transformed. Some authorities also believe that the role of women underwent a significant and negative change because of the horse. Although different tribes used horses to greater or lesser extents, the horse changed Native American culture forever. What is even more remarkable is that the change took place within a few decades.

The modern horse was brought to America by the Europeans, especially the Spanish. The most numerous were the barb horses, small and sturdy animals bred to survive in North Africa. The Spanish quickly found that these horses were well suited to the Southwest. By the mid-1600s, thousands of horses were being raised on Spanish rancheros. Native Americans were forbidden to own and ride horses, but even so, many learned how to ride and handle horses as a part of their work for Spanish overlords. When the Pueblo Rebellion of 1680 forced the Spanish out of New Mexico, thousands of horses were left behind. Many escaped, while others were taken by the Native Americans for their own uses. These horses quickly made their way northward into the grassy southern plains.

Tribes such as the Comanche adapted to the horse and helped spread them to other tribes. By the 1730s horses were being used by tribes on the Missouri River. Forty years later, tribes as far away as the Canadian prairies had horses.

Some tribes adapted to horses more than others. For all tribes on the Great Plains, however, the horse brought the end of an old way of life and a revolutionary new lifestyle. Tribes that had previously been nomadic had depended upon dogs and human carriers to move from place to place. Material goods were limited, as was the area over which they ranged. Women raised some crops and gathered other foods to supplement meat brought in by male hunters. Hunting was done on foot. Bison in particular were hunted by stealth or by large numbers of people driving them over cliffs or into confined spaces. Women and children as well as men were required to play an important role in these hunts.

The horse promoted a more mobile life. Using travois, horses could drag large loads, encouraging the accumulation of material goods. Groups of people were able to roam farther as well.

Tribes learned to follow the bison herds, which became the most important source of food and goods. When the bison gathered in large herds during the spring and summer, related groups gathered as well and staged massive hunts. During winter, the tribes broke into smaller groups that followed smaller herds of bison into sheltered valleys. Hunting was done from horseback and almost exclusively by men. A wider range of movement led to more conflicts with neighboring tribes for hunting grounds and grazing for horses. Warfare between Native Americans increased, as did more peaceful forms of contact. Trade increased, and most tribes on the plains adopted aspects of others' cultures, including religious practices such as the Sun Dance.

The dependence on horses changed Plains Native American society. Horses became the measure of a man's wealth and status. Horses were given as gifts or as a price for a bride. Obtaining horses from other tribes became a favored way of making war or of proving one's manhood. Successful warriors were those with many horses. Those who had to walk were looked down upon in more ways than one. As tribes adopted more nomadic lifestyles, those with more horses could move more material goods. They tended to accumulate more, trading their horses for such products as firearms, tobacco, liquor, tools, and other goods from white men.

Hunting changed radically with the horse as well. Nomadic tribes followed the rhythms of the bison, but hunting became a display of virility and sport as well as a necessary chore. A good horse allowed a hunter to ride next to a bison and kill it with an arrow or lance thrust. Women were relegated to a minor role since they did not kill the bison. Displays of prowess often led to hunters killing more bison than necessary.

Dependence on the horse had a significant ecological impact as well. As Native American horse herds increased in size, they came into direct competition with the bison herds. Both species depended on the grass that grew on the plains and had to locate it during winter in sheltered areas. Some authorities believe that the bison population was declining before 1840, when white hunters began to make inroads. Tribes also began to divide into smaller groups because large herds could not be supported in

one location. As a result, tribes on the plains tended to develop into smaller nomadic groups that depended more on raiding than previously.

The Chamorro and the Columbian Exchange in the Marianas

For two centuries (1668–1898), Spanish rule in the Mariana Islands (North Pacific Ocean) transformed the island society so thoroughly that by the nineteenth century its traditional Pacific culture was hardly discernible. The Marianas became the first island group in the Pacific to be colonized by Westerners and to lose most of its traditional culture. This pattern was imitated elsewhere in the Pacific as navigators charted the island groups of Micronesia, Polynesia, and Melanesia, all of which eventually became possessions of foreign governments half a world away. The peoples of Guam and the Northern Mariana Islands (Chamorros or Chamorus) are particularly striking examples of the Columbian Exchange in which indigenous peoples were overwhelmed by their European conquerors.

During his circumnavigation of the world in 1521, Ferdinand Magellan stopped briefly in the Mariana Islands, and in 1563 Admiral Miguel Lopez de Legaspi took possession of them in the name of the Spanish king. By 1600 the islands had become an important refreshment stop for Spanish trading ships plying the Pacific between Spanish-controlled Mexico and the Philippines. It was not until 1688, however, that a permanent

➤ GOVERNOR JOSÉ QUIROGA ON THE DEPOPULATION OF THE MARIANAS

The second Spanish governor of the Mariana Islands, José Quiroga, arrived in the islands in 1680 for the sole purpose of punishing the resisting Chamorro population and putting an end to the rebellions on Guam. He attacked and burned their houses. He pushed them into the mountains, where he captured and hanged them in the presence of their followers. In 1684 he forced the islanders of Saipan and Tinian into submission. For 16 years Quiroga served as governor or commander of the military forces. He retired on Guam and in 1720 complained in a letter to the Spanish Crown of the drastic reduction in population and the state of misery in which the Chamorros lived. Quiroga lay the blame squarely on the numerous epidemics brought by the annual trade ships and the forced labor imposed upon the islanders and not upon the casualties resulting from the Chamorro wars.

—Robert Craig

Spanish settlement was established. In that year, a group of Catholic missionaries headed by Father Diego Luis de Sanvitores (with the backing of a group of soldiers) landed on the island of Guam to bring Christianity to what they considered a backward and degenerate people. At first the islanders welcomed their guests warmly, but soon conflicts broke out between the two cultures. Father Sanvitores and several other missionaries were killed, and the soldiers took action. For the next 30 years, a Chamorro War ensued during which time revolts, sieges, the murder of missionaries, and the burning of churches were countered by the governor's armed forces. By 1700 the Spanish had subdued the population and had forcibly moved the Chamorros from the Northern Marianas to Guam so that the colony could be better controlled.

War and disease, however, had decimated the population. By 1710, only 3,539 Chamorros were living in the islands. Although some early visitors to the islands estimated the original population to have been about 100,000, contemporary scholars, using more informed

sources, place the population between 35,000 and 40,000. Even at 40,000, the loss of population between 1668 and 1710 is devastating, but to assume that the loss was a deliberate attempt by the Spanish to exterminate the Chamorros is not supported by a detailed study of the period. Indeed, wars contributed to a loss of lives—certainly more Chamorros than Spaniards—but the Spanish had come to convert and civilize, not to exterminate. Furthermore, the islanders provided food and labor not easily obtained in the middle of the Pacific. The culprit may have been Western diseases—measles, small pox, and scarlet fever—for which the islanders had developed no immunity. Untold hundreds if not thousands died each year after the Spanish galleons visited the islands.

By 1700 a forced peace had been established, but by now the Chamorros had lost pride in their traditional culture, and their whole world had been turned upside down. Once they lived in small tribal hamlets, organized in matrilineal (mother's ancestral) groups, where they performed subsistence farming and went deep-sea fishing in their fine outrigger canoes. Now, they lived in hamlets or small towns and tilled small plots of land on the outskirts. Land ownership had been completely changed, and the government claimed over half of it. Towns were laid out in Spanish fashion—a church and large plaza in the center—with narrow streets and thatched-roof houses. Their new tempo of life was determined by church bells that rang out the time for prayers and the time for work. Men were required to work two days in the fields growing corn (maize), melons, and root crops and to raise pigs and poultry for the support of the governor and the military. The women collected copra (coconut meat) to feed the pigs and wove mats and sails of pandanus to be sold in the Philippines. A full day's work might earn them two or three leaves of tobacco imported from the Philippines. At that rate, it took four to six months to purchase a simple pair of pants.

The Chamorros never seemed to recover from the Spanish impact. The colony languished in a tedious and monotonous way of life until 1898, when the United States seized Guam at

the beginning of the Spanish-American War and Germany purchased the Northern Mariana Islands. The Japanese seized all of them in 1941 and initiated a strict military regime. After World War II, the United Nations (UN) awarded the islands to the United States as a Trust Territory. Since then, Guam and the Northern Mariana Islands have both developed relatively free and democratic governments, but only remnants of their proud traditional way of life survive.

■ Introduction: Demographic Changes

Between the fifteenth and eighteenth centuries, the world's population rose from between 350 and 400 million, to about 700 to 750 million. Some areas were subject to rapid growth (e.g., China and Europe), while others experienced spectacular declines, most notably the indigenous populations of the Americas. The overall increase was remarkable, considering that in the preceding centuries human population tended to double only every two thousand years. During this period there also were massive migrations on a global scale. Several million Europeans migrated to the Americas, Africa, and Asia during the European Age of Discovery and Expansion. In the seventeenth century, following the Mughal conquest of India, tens of thousands of Muslims migrated from Afghanistan, Iran, and central Asia to the Mughal court. In China, booming population as well political and economic problems led to massive internal migrations to and colonization of Mongolia, eastern Turkestan (present-day Xinjiang), Tibet, and southeastern Siberia.

Simultaneously there was an accelerated exchange of people, animals, plants, microbes, cultures, and ideas. Known today under the general rubric of "the Columbian Exchange," the process was stimulated by European desire for trade and the acquisition of territory. It began with Portuguese voyages along the coast of Africa in the

mid-fifteenth century and expanded with Christopher Columbus's encounter with the Americas in 1492 and the arrival of Vasco da Gama in India in 1498.

The exchange ensued from trade and European settlement in the Americas, coastal Africa, the Indian subcontinent, and Southeast Asia, African displacement to the Americas, and some Asian emigration to the Americas and Africa. While only a small number of original Americans left the Western Hemisphere, a wide variety of plants did. American crops like corn, beans, squash, potatoes, tomatoes, peanuts, chilies, cacao, manioc (cassava), sunflowers, and tobacco crossed the oceans, doubling the world's food supply within one hundred years. In return, such Old World staples as wheat and other grains, grapes, olives, okra, citrus fruits, sugar, palm oil, bananas, and rice traveled to the Americas, along with domesticated cattle, horses, sheep, goats, pigs, chickens, large dogs, cats, bees, and rats. With the exception of the turkey, the Americas contributed few animals to the rest of the world.

One of the most dramatic exchanges was disease. Beginning in the sixteenth century, smallpox, measles, influenza, yellow fever, malaria, cholera, and other Old World afflictions wreaked devastation on virgin soil (nonimmune) populations in the Americas and Oceania, producing

mortality rates of up to ninety percent in most regions. As far as researchers can tell, and this is still subject to debate, the only disease to reciprocate was a virulent strain of syphilis from the Americas, which cut a path across the world in the sixteenth and seventeenth centuries before becoming one of the best-known sexually transmitted diseases in history.

The impact of disease exchanges was profound. High human mortality facilitated the conquest and settlement of Europeans throughout the Americas and Oceania. And because European settlers required a steady supply of labor for their economic ventures, when indigenous sources became scarce millions of Africans were enslaved to replace them.

Recent studies reveal that between 1450 and 1850, about 12 million Africans were transported as slaves across the Atlantic. The Middle Passage, as this crossing became known, claimed the lives of some 10 to 20 percent on the slave ships, while about 10 to 11 million Africans eventually arrived in the New World. Yet, these numbers only convey a partial picture since they account for the Atlantic slave trade only. An estimated 3 million Africans were sold

and transported through trans-Saharan, Red Sea, and east African trade routes as well.

Africa suffered heavily as the slave trade depopulated many regions, fundamentally altering the economic and political makeup of much of the continent. The resulting intermixture of American, European, and African peoples transformed the ethnic makeup and cultures of the Americas dramatically. Ideas and religious beliefs also crossed the oceans, implanted in the Americas and coastal Africa and Asia by soldiers, traders, settlers, missionaries, and slaves. Today the peoples of the Americas and several areas of Africa and Oceania are considered predominantly Christian, though many ceremonies clearly exhibit indigenous or African characteristics. Christians are significant minorities in several regions of Asia. In the middle of the eighteenth century secular ideas generated in the European Enlightenment also made their way to the rest of the world, above all concepts of political liberties, separation of church and state, and nationalism. These had a profound impact on the entire world, stimulating the American Revolution of the 1770s and the subsequent Haitian and South American revolutions, and they

Estimated Slave Imports into the Americas, 1519–1866 (adapted from Paul Lovejoy, Transformations in Slavery: A History of Slavery in Africa [1983]). Numbers refer to millions of people; e.g., 4,500 = 4,500,000.

still influence international relations. In multiple ways the Columbian Exchange integrated the globe and set in motion forces that continue to challenge the world today.

West Africa's Tears—Population Movement and Loss

Over the past several decades, a consensus has emerged that around 12 million people were brought to the Americas from the African continent during the era of the Atlantic slave trade. This number, however, does not necessarily provide adequate insight into the demographic impact of the slave trade on West and Central Africa, the regions of the continent most heavily involved in the trade.

First, the estimate presented above only reflects those who arrived alive in the Americas and does not include those who died during the Middle Passage. Conservative estimates place this death toll at around 15 percent, or roughly 2 million people. Thus, some 14 million people left the continent bound for the Americas. Further, it is important to note that the estimates of this number do not reflect the people who were killed prior to being placed upon slave ships for transport. Estimates suggest that perhaps 10

percent of captives died while awaiting transport in coastal ports, where conditions were often crowded and disease could easily spread among captives. Thus, perhaps more than 1 million lives were lost even before the Middle Passage. Similarly, it is estimated that perhaps 25 percent more were lost during the continental passage to the coast. Here, captives were often forced to walk for weeks over difficult terrain while shackled and exposed to the elements. If this mortality rate is correct, then another 3 million or more lives were lost at this stage of the slave trade. Finally, given that violent warfare was the most common mode of capture and that people often fought to the death to protect themselves and their families from enslavement, estimates place the likely mortality rate from capture at around 40 percent. As such, it is likely that around another 6 million lives were lost at this stage of the trade. Altogether, it is possible that for every individual who was transported to the Americas, another was lost. This means that the total African population loss during the Atlantic slave trade was likely around 24 million. This number is all the more stark when placed in the context of an estimated total African population of around 70 million in 1800.

Notably, studies suggest that the African population did not necessarily decline during the era of the slave trade. Rather, it appears that the introduction of new crops from the Americas, such as maize and cassava, helped provide enough surplus food to allow population growth to offset the loss of millions to the slave trade. However, this also means that Africa did not benefit from the surge in population growth experienced by Europe and Asia during this same period. Historian Patrick Manning has estimated that the African population in 1900 was actually half what it might have been if there had been no Atlantic slave trade.

It is important to note that the slave trade also resulted in significant demographic shifts within West and Central Africa. In order to take refuge from the threat of enslavement, many populations moved into more defensible regions, including deep forests and highland regions. This, however, necessitated moving out of the more agriculturally and economically productive regions where people had long preferred to

live. This shows how the slave trade could have significant long-term effects on African economies. Unexpectedly, the slave trade also likely resulted in a shift in African populations away from the interior and toward concentrations near the coasts. This was in part because the demand of the Atlantic slave trade was focused on males, and female captives were often retained by slave-trading societies there. The addition of large numbers of women to these societies may have resulted not only in expanded populations but also in an increased practice of polygyny as well.

Christian and Muslim Responses to Epidemics and Diseases in West Asia

From 1450 to 1770, Christian and Muslim societies of West Asia were troubled by a myriad of epidemic diseases. Among these diseases were leprosy, typhus, smallpox, and bubonic plague, and later diphtheria, measles, syphilis, and gonorrhea. However, social and communal responses to plague in particular are most significant because it spread fast and caused high mortality rates, and consequently had a more radical influence on West Asian societies' attitudes and practices. In the mid-fourteenth century, during the initial outbreak of plague known as the Black Death (1347–1352), at least a quarter of the population of West Asia was killed. Following the Black Death, a series of successive plague outbreaks continued to affect the region until the beginning of the modern era.

In the past, historians have tended to explain the attitudes of Christian and Muslim societies toward epidemic disease on the basis of assumed regional and religious differences. For example, they have stressed the important role

of quarantine practices in Christian Europe and the fatalistic attitudes of Muslim societies in this respect. Nowadays, however, scholarship addresses the problem by emphasizing commonalities in social behavior and communal responses. These ranged from frenzied flight, rioting, ostentatious religious behavior (communal processions and prayers), an intensification of apocalyptic fears, and perhaps most importantly, governmental efforts to establish regulations for the purpose of monitoring and fighting plague.

For the most part, Christians and Muslims alike saw flight as the first resort in case of a plague outbreak. One form of popular wisdom, sometimes reinforced by plague treatises, recommended that people flee early, go far, and return late. Since Christian teaching interpreted plague as an expression of divine wrath, Christian authorities denounced flight and preached the necessity of repentance, fortitude, and prayer. Similarly, although Muslim teaching also prohibited flight, there is some evidence that Muslims fled from the plague anyway. During and in the immediate aftermath of the Black Death, Muslim legal scholars wrote treatises that sought to legitimize the prohibition on flight by maintaining that plague was a blessing or mercy of God and a means of martyrdom for the believer. In contrast to the legal opinion of these earlier Muslim scholars, plague treatises written in the Ottoman empire from the fifteenth century onward recognized the notion of contagion and granted legitimacy to the need to exit a plague-infested city in search of clean air. Of course, flight was not an option for all. The urban lower classes, not owning summer residences in the countryside, were bound to stay in deserted cities where they suffered from severe hunger and often turned to crime for survival.

The difficulties governments encountered in their effort to reestablish law and order in the cities fostered many experimental measures for the purpose of monitoring, controlling, and fighting epidemic diseases. From the fifteenth century onward, West Asian governments adopted a series of solutions that included the implementation of quarantine regulations, the systematic recording of daily death tolls, the relocation of burial areas outside city walls, the enforced consistency of burial practices, sanitation improvements in

► LIVING WITH THE PLAGUE

Plague epidemics were particularly severe in the early modern Islamic world during the sixteenth and seventeenth centuries. There were several major outbreaks during the sixteenth century, the more important ones taking place in 1520–1522, 1534–1535, 1544–1545, 1553–1556, 1561, and 1565–1566. Yet the most terrible outbreak of the sixteenth century started in the 1570s and continued more or less until the end of the sixteenth century. Being particularly strong in Istanbul, Anatolia, the Balkans, Egypt, North Africa, and in Safavid and Mughal lands, this vast pandemic affected almost all parts of the Islamic world, as well as Europe. The seventeenth century also witnessed several major outbreaks: 1603, 1611–1613, 1620–1624, 1627, 1636–1637, 1647–1649,

1653–1656, 1659–1666, 1671–1680, 1685–1695, and from 1697 until the early years of the eighteenth century. The outbreaks of the eighteenth century were reported as mostly minor outbreaks; the major ones took place in 1713, 1719, 1728–1729, 1739–1743, 1759–1765, 1784–1786, and 1791–1792. Plague epidemics gradually disappeared during the course of the nineteenth century. The major outbreaks of the nineteenth century took place in 1812–1819 and 1835–1838. It is commonly held that the disappearance of plague epidemics in the nineteenth century in the Islamic world was the result of the adoption of quarantine measures and their implementation in the Ottoman empire from 1838 onward.

—Nükhet Varlık

urban areas, and the inspection of water sources. Becoming increasingly more structured and standardized over time, these early efforts may have provided a basis for the emergence of the public health systems of modern states.

During and immediately after the Black Death, medical theories rarely diverged from the precepts of both Greco-Roman and classical Islamic medical traditions. Both Christian and Muslim physicians stressed the importance of preserving health and restoring the balance of humors during plague outbreaks. Physicians continued to recommend eating a well-balanced diet, regular bleeding and purging, and moderation in physical exercise, sexual intercourse, sleep, and emotional dispositions. Concurrently, early modern plague literature offered a multitude of treatments and recipes for often ingenious and purportedly efficacious remedies. Allegedly preventive substances, such as theriacs, *terra sigillata*, and bezoar stone were in high demand in the markets of West Asia. Furthermore, people there also resorted to astrology, alchemy, and magic in a desperate search for protection and cure. Prayers, amulets, magical incantations and formulae, among others, acquired a rich significance in the plague literature and became profoundly integrated into the daily life of Christian and Muslim societies alike.

Population Growth in Early Modern India

Between 1600 and 1800, the estimated population of India rose 33 percent, from 120 million to 160 million, an annual growth rate of .14 percent. The rise in India's population was due to several factors: improvements in medicine and technology; the introduction of new foodstuffs, such as maize, from the Americas; a period of relatively stable rule, first under the Mughals and later under the British and other European powers; and the dwindling effects of the Black Death.

Though European medicine was, by modern standards, primitive during this period, the

► THE BENGAL FAMINE OF 1769–1770

The Bengal Famine of 1769–1770, with the effects continuing until 1773, was one of the worst in Indian history; approximately one-third of the population (10 million people) of the province of Bengal died. The famine was caused initially by drought, but it emerged and was exacerbated by the policies of the British East India Company, a company that had begun to rule the region following the Battle of Plassey in 1757.

The main priority of the company was the raising of revenue; despite this, the company was unable to make its annual payment of £400,000 to the British government in 1767. These financial difficulties placed immense pressure on the company to maximize tax collections. However, efforts to increase revenue had a limited effect due to corruption among company employees. In 1769 Richard Becher, an adviser to the governor, warned that the increased demand on farmers was causing widespread poverty throughout the province, as the province's economy was already in poor shape when the drought hit.

As the famine began, the large death toll (and subsequent shortage of labor) meant that about

one-third of the farmland went out of production. The food supply shrank further, and many peasants were reduced to eating grass and tree leaves. The death toll worsened further as a smallpox epidemic broke out in the spring of 1770 in the provincial capital of Moorshedabad.

Through the use of military force, the company actually managed to increase the amount of revenue it collected during the famine, receiving more revenue in 1771 than before the famine in 1768. However, it took more than a generation for the population and economy to recover in the region.

introduction of European medicines and methods of treatment combined with indigenous Indian practices worked to increase the range of possible treatments for disease and injury. Technological advances that promoted population growth included maritime innovations that cut travel time and thus increased the availability of food over a wider area. With increased technology (and the resulting increased production of goods and extraction of natural resources) came increased trade. This in turn spurred population growth, as greater wealth meant greater access to food, medicine, and decent living accommodations. Maize and potatoes, introduced to India by the seventeenth century, proved to be readily adaptable to Indian soil, increasing the amount of calories and other nutrients that the average Indian consumed and thereby promoting a longer lifespan. Though warfare did periodically erupt throughout India during the early modern period, the massive cataclysmic invasions by outside peoples, so characteristic throughout

Eurasia during the ancient and medieval periods, largely ceased, partly due to the presence of a stable and relatively centralized government in India. Finally, the Black Death, which hit India with terrible effects in the fourteenth century, was largely gone from South Asia by the early modern period, and the Indian population, like its European and Chinese counterparts, began to undergo a natural recovery.

Nevertheless, this population increase, though significant, was considerably lower than similar population booms experienced in Europe and China during the same period. This discrepancy is primarily due to environmental factors. Much of India lies in a tropical or subtropical zone, where disease is more common (e.g., bacteria thrive in such wet conditions). In addition, fatal natural disasters, such as massive flooding caused by monsoons, are much more common in India than in Europe and China. Some historians also theorize that fertility declined in India during the early modern period due to cultural

factors (such as the lower frequency of widows remarrying), but this is unproven.

China's Population Boom

Since its formation as an empire in 221 BCE, China has always been the most populous country, but the growth in population during the period 1450–1770—during the Ming dynasty (1368–1644) and the first half of the Qing dynasty (1644–1911)—was more like an explosion. Up through 1770 China escaped periods of major upheaval, with the exception of the last 60 years of the Ming and the first 40 years of the Qing. This 100 years of peace helped the population rebound from the various wars and peasant rebellions that had consumed the Ming. But increased food production and bursts of commercialization leading to urbanization—both aided immensely by the Columbian Exchange—played the largest roles in the boom.

The Ming government and to an even greater extent the Qing government sponsored irrigation, canals, and flood-control projects at massive rates. The Qing alone essentially doubled the number of irrigation projects ever created throughout Chinese history. With the advent of new strains of rice from Vietnam, the far south of China was able to grow three crops a year and in most of the Yangzi River valley two crops a year. To allow for the planting and harvesting of more acreages of rice in the humid, hot, and productive south, peasants worked to terrace the steep hillsides of the region, creating myriad thin strips of farmland. To double the crop yields for rice, the Chinese turned to increased human care and better fertilization, which included soybean cake and nightsoil (human excrement). More peasants working to eliminate weeds from the rice fields meant a larger yield per acre, as did the increase in nightsoil available to the plants due to a larger family. But the lack of monsoon rains in most northern and western provinces meant that not all of China grew rice.

The Columbian Exchange provided crops to grow where traditional Chinese ones could not. Potatoes provided calories to those in the north to add to the traditional meals of wheat, sorghum, and millet, while in the south sweet potatoes enriched the rice diet. Both kinds of potatoes grew well in what the Chinese had previously considered unfit sandy soil. Both kinds of potatoes provided the peasants more calories per acre grown than did grain, something that Europeans quickly discovered as well. The Chinese planted maize (corn) where enough rain fell in areas otherwise too steep to terrace. Finally, peanuts came to provide protein, which, like soybeans, allowed peasants lacking the money to purchase or grow animals for slaughter to eat more healthily. All these crops, plus the new strains of rice and extra territory conquered by the Qing military, led to a doubling of acreages of food crops. More food meant larger families, which in the next generation created the need for more farms.

Population growth was also made possible by the cycle of urbanization and commercialization, although to a far lesser extent than food production. Silver mines in Europe funded extravagant purchases of silk and fine porcelain from China in the early Ming. With the advent of the Columbian

➤ PEASANT PROBLEMS WITH COMMERCIALIZATION

When silver flowed easily into China, the Ming government combined a large number of peasant taxes into the Single Whip taxation, a simple tax on land payable only in silver. The term for the tax was a pun on “combination in one item,” which sounded like “single whip” in Mandarin Chinese. Moving away from in-kind taxation made income for the central administration more predictable. It also made life difficult for peasants when severe weather destroyed crops or the price of grain fell so much that a high percentage of the harvest had to be sold for silver to pay taxes. People in some of the most fertile areas of the Yangzi River delta became so specialized at growing cash crops of indigo, cotton, or high-quality rice or working mainly on making silk or porcelain for sale that the people there had to import food! When these commodities dropped in value, peasants could starve.

—William Ashbaugh

Exchange, the silver became a flood, mainly due to its discovery in the Americas and the use of Manila in the Philippine Islands as a trading port to connect the Chinese and Spanish empires. Because the Chinese never coined silver, using it at first in weighed amounts to conduct trade, by the time of the late Ming and early Qing China was awash with Spanish pesos (also known as pieces of eight or Spanish dollars, later called the Mexican silver dollar). Silver was so easily obtained that the Chinese government combined a large number of peasant taxes into the Single Whip taxation, a simple tax on land payable only in silver. Merchants and the artisans who needed to satisfy their pleasures moved to ever larger cities (Greater Nanjing housed 2 million in its early Qing years, while Greater Beijing housed around 1 million) or helped build up trading cities along rivers or near the coast. Merchants sailed their ships from port to port or upriver to conduct trade within China, which was still far larger and more valuable than foreign trade.

Determining the growth rates for China's historic population boom requires educated guesses, as there were pressures on officials conducting the census to underreport and later to overreport. It appears likely that from a 1650s figure of approximately 100 million Chinese, the population grew in 1741 to 142 million and surged ahead to 243 million in 1778. By the nineteenth century, China's population finally overwhelmed the increased crop production, leading to large-scale peasant and religious uprisings by the hungry, weakening the Qing and allowing partial subjugation to the West.

The Great Epidemics in China, 1586–1589 and 1639–1644

For centuries after the so-called Black Death swept across Eurasia and North Africa, China continued to be hit by widespread epidemics. Among them, two were especially grave: one took place in the 1580s and climaxed between 1586 and 1588, and the other lasted from 1640 to 1644. Both left behind trails of social devastation, particularly the second one that facilitated a violent dynastic shift.

Frequent and widespread epidemics were a phenomenon in the entire premodern world. Meteorologists suggest that the period from about 1300 to circa 1850 constituted the Little Ice Age, with the average temperature dropping by several degrees Celsius, which caused a shortening of the growing season and crop failures. Concurrently the changing climate also had a tremendous impact on nomadic societies in northern Eurasia. These nomads depended on livestock for their livelihood; as their livestock went hungry or died due to the shrinking grazing areas, many of the nomads were driven out of their home bases in search for alternative food supplies. As they reached out to agricultural societies in the south, contacts between different peoples in these two different societies became more frequent and intense. Such intensified contacts led to growing exchanges of commodities, ideas, and genes, but the most significant exchange was probably of germs and viruses. Thus, many epidemics and pandemics broke out across all of Eurasia. Living closely to livestock and on the steppe, the nomads developed at least partial immunities to many diseases originating in and common to their environment or at least developed coping devices by which they could avoid contamination, but agriculturalists to the south lacked both.

Available sources suggest that as was true of the great fourteenth-century pandemic, the Black Death, the epidemics that hit China during the 1580s and 1640s were both caused by the bacterium *Yersinia pestis*, the germ of bubonic plague. The bubonic organism is often carried by rats, mice, and other burrowing rodents and is common on the steppe; it is highly contagious and deadly to humans when no proper medical

care is available. In addition to their cultural taboos and possible partial immunity that protected them somewhat from the ravages of the plague, the nomads also enjoyed another advantage: their steppe land was sparsely populated, and the chance of an epidemic was greatly reduced. But the story for the Chinese was entirely different. Most cities and towns in northern China were crowded, and their hygiene was never as good as it should have been. As a result, the bacterium found a haven in which to thrive. It was not just a coincidence that the Chinese epidemic of the 1580s first occurred in Shanxi Province, and the epidemic of the 1640s hit Hebei Province. Both were located right next to Mongolia.

According to records by contemporaries, including Jesuit missionaries from Europe who witnessed these two epidemics, the victim usually developed the syndrome of a swollen neck, a classic bubonic plague symptom. Unaware of the cause, the Chinese then referred to the disease as “huge-neck plague.” It was indeed a killer. In 1582 when the huge-neck plague broke out in Shanxi, nine of every ten households in the city of Datong, the capital of the province and probably northern China’s most populated city, caught it, and 20 percent of these patients died. Between 1586 and 1589 the huge-neck plague spread to Beijing, the capital of the ruling Ming dynasty, and from there it further spread to the southern provinces all the way down to the Yangzi River basin. The plague was so contagious that an entire family might be wiped out. Once a person caught the plague, therefore, even the closest family often did not dare to attend the patient in fear of catching it as well. In some areas up to 40 percent of the population perished. The epidemic of the 1580s proved to be a turning point for the fortune of the Ming, for it accelerated the deterioration of the already rotten ruling dynasty.

But it was the epidemic of the 1640s that arguably had much more dramatic political and social consequences. The epidemic first started in the south of Hebei near Beijing, also a densely populated region. By late 1643 it spread to Beijing, a city with a population of probably close to 1 million. At that time the Ming dynasty was battling two enemies, rebels from the western

➤ HOW DO WE KNOW MING CHINA’S POPULATION?

It is difficult to accurately calculate the population size and fluctuations of a premodern society such as Ming China. So far as China is concerned, most historians first look at governmental household registrations. The Ming government kept a reasonably complete record, known as *huang ce* (“yellow volumes”) for tax purposes. But the *huang ce* reveals only part of the whole picture, for many factors might have affected these recorded numbers. Well-connected individuals might underreport their family members to evade higher taxes, and at times female members were left out. Beyond that, throughout the Ming period increasing global connections and changing social and environmental conditions had an impact on the population that was not always accurately reflected in official census records. The introduction of new crops from the Americas, such as sweet potatoes and peanuts, led to a steep growth of the population and set in motion widespread migrations, both internally and externally. Meanwhile, warfare and natural disasters decimated residents in affected areas. An epidemic swept across the Grand Canal area in 1641 and killed an estimated 90 percent of the residents in Zhejiang, for example. Those who survived often turned into “drifting people,” uprooted from the land. Conceivably, the Ming government lost count during such constant and rapid demographic modifications. As a result, historians must dig deeply into additional sources, such as reports from local officials, records concerning the effects of epidemics, local gazetteers, and even private records to piece together a more accurate picture about Ming China’s population at any particular time.

—Yi Li

provinces led by the Li Zicheng and the nomadic Manchus from the northeast. Even so, the situation did not initially seem at all that desperate for the Ming. Its troops had just decimated the rebels in the Ningwu Pass battle; the Manchu emperor, Hong Taiji, had just died; and the Ming emperor Chongzhen (r. 1628–1644), although by no means a gifted leader, was nonetheless diligent at his job. But in early 1644 all had changed. First, the rebels approached Beijing and seized it easily, and the 276-year-old Ming dynasty thus

died when its last emperor, Chongzhen, hanged himself. Then the victorious rebels launched an expedition on Wu Sangui, the Ming general who refused to surrender. In the Shanhai Pass battle the offense of the rebels suddenly collapsed, despite their superiority in numbers. All of these dazzling shifts of power were followed by the conquest of all of China by the nomadic Manchus, who had a much smaller force. Tipping the balance among all these contesting forces was, among many other things, the bubonic plague, which climaxed in early 1644 in Beijing, paralyzed the defense of the capital, and sent the Ming to a sudden death. Then it caught the rebels, who subsequently entered Beijing and delivered the Ming an equally deadly blow. All obstacles were thus cleared for the Manchus to enter China and claim the Mandate of Heaven by establishing the Qing (Pure) dynasty (1644–1911).

Population Fluctuations in Europe

From the fifteenth to the eighteenth centuries, Europe's population experienced remarkable growth despite major fluctuations. An improved diet, the result of more land put into cultivation and the influx of New World foods, and more efficient agricultural techniques increased the life expectancies of many Europeans. Migration to urban areas in the wake of commercialization and the growing wealth and prosperity of towns also contributed to a long-term rise in population. However, other forces complicated this pattern of long-term demographic growth.

Periodic poor harvests punctuated a counter-trend in sporadic yet widespread famines. Large-scale warfare and outbreaks of disease also led to considerable declines. Moreover, new lands brought into cultivation and the extraction of natural resources displaced forests, marshlands, and wildlife, compromising fertility and biodiversity throughout Europe.

Long-term demographic growth from the fifteenth century to the eighteenth century was characterized by steady expansion since the ebbing of the Black Death (ca. 1400). By 1400 after a steady but long recovery over several decades, population had recovered to the point of preplague demographic estimates (between 60 million and 65 million people). Europe's population grew from approximately 84 million in 1500 to 146 million in 1750. This growth lasted well until the end of the sixteenth century, when the disastrous seventeenth century, with its Thirty Years' War (1618–1648), a new plague cycle, and a series of famines, led to the leveling off of the population. In the century that followed, Europe's population again experienced widespread growth due to the withering of the plague, migration to the Americas (which lessened the stress on domestic population), and increased food supplies as the result of more efficient agricultural methods.

Disease continued to disrupt the general trend of population increase, however. Outbreaks of the plague occurred from time to time, typically in isolated regions, and eruptions of typhus, syphilis, smallpox, and malaria further checked population growth, disproving conventional wisdom that these epidemics struck congested urban areas with greater severity and frequency. Poor harvests and flawed food-distribution networks sporadically triggered local and regional famines. Early modern warfare, with technologies and tactics that made conflict both more widespread and more deadly, also contributed to the decline and stagnation in population, especially during the leveling-off period of the early to mid-seventeenth century, with its Thirty Years' War and English Civil War (1642–1649). However, evidence shows population growth at a steady pace despite the obstacles mentioned, doubling the European population from 1500 to 1800.

THE GREAT PLAGUE OF LONDON, 1664–1666

The Great Plague was one of the more catastrophic outbreaks of the bubonic plague that swept through London and much of England in the early seventeenth century. The notorious Black Death, as it was known, was a recurrent epidemic throughout much of Europe since its first appearance in 1348, which decimated an estimated one-third of Europe's population. The Great Plague of London led to the deaths of approximately 100,000 people from 1664 to 1666. While the epidemic affected to a great extent the less prosperous outer areas of the capital, it eventually spread to the more affluent sections of central London. The Stuart monarch Charles II was forced to leave London for Oxford along with his court. Cases continued to occur through many parts of England for several years afterward, but this was the last major outbreak that occurred. The Great Plague of London is an example of the continuing threat of disease in the midst of steady population growth in Europe.

—Abraham O. Mendoza

Title page of a bill of mortality for London from the Great Plague of London, based upon the statistical analysis of John Graunt. (Jupiterimages)

The growth in the European population is also attributable to the increased settlement and cultivation of land. Since the early Middle Ages swaths of uninhabited and sparsely inhabited lands had been brought into production. During the fifteenth century more land was brought under European possession, either through warfare (the *reconquista* in Spain and German expansion in the Baltic and eastern Europe) or through reclamation (Dutch dam and dike systems, German and English draining of marshes), and deforestation. While much of this land had been in European possession for centuries, this period was one of increasing development of formerly virgin resources. This added productivity and led to an increased food supply, which in turn benefited the growing population of Europe through adequate nourishment. However,

these trends did take a tremendous ecological toll on the landscape of Europe, destroying forests and marshes, causing soil erosion through inadequate agricultural practices, and limiting the remaining range for European wildlife.

Early modern Europe underwent growing urbanization, fueled by economic prosperity in the towns and cities and increasingly dire conditions in the countryside. The expansive growth of towns and cities as major population centers, due to massive commercial expansion, also required land and the extraction of resources, thus further contributing to changes in the European landscape. Trade with the American and East Indian colonies fueled the further economic expansion of urban mercantile centers and ports and attracted people from the countryside into towns and cities. Push factors such as the

Enclosure Acts in England, which cut off communal lands from peasant use, freed former rural residents to migrate into towns and cities.

European Emigration— World and the Americas

Following the initial voyages of discovery, European countries developed distinct patterns of immigration to the Americas and the rest of the world. From the sixteenth to the eighteenth centuries, Spain, Portugal, the Netherlands, the British Isles (England, Scotland, and Ireland), and France developed distinct immigration patterns, shaped by their colonial possessions, their global economic investments, and domestic factors.

Imperial Spain (the kingdoms of Castile and Aragon) was able to send vast amounts of colonists into the Americas during their three centuries of colonial rule (1500–1800). An estimated 750,000 Spaniards immigrated during this period to the Americas and created a stable Spanish society that sustained itself through continued emigration from Spain and intermarriage between Spanish men and indigenous American women. The Spanish encountered native societies whose lower social orders could be utilized as a workforce to their benefit. They also settled in highly developed highland regions (Mexico, Peru, Argentina) free from health hazards for Europeans, in contrast with those found in southern tropic regions. Most of the Spanish migrants were skilled professional men seeking better opportunities abroad at a time when Spanish domestic economic stability was uncertain. Other migrants pursued better social and economic advancement in Spanish America that would not have been available in the Spanish realms.

Portugal had colonial possessions in the Americas (specifically Brazil) and along the coasts of Africa, South Asia, and Oceania. Similar to the Spanish dominions, Portugal's empire relied on trade and commerce and thus necessitated settlement. Portugal's commercial concerns in Brazil, Africa, and Asia necessitated fortified positions to maintain Portuguese control over trade in slaves and spices, which in turn created a demand for soldiers, merchants, and sailors. From 1500 to 1800, an estimated 3 million Portuguese settlers left Portugal for the empire. In contrast with the Spanish, Portuguese settlers had a shorter life span, given their preference for the disease-ridden tropics. They also did not intermarry at the same rate as the Spanish, failing to create a creole (mixed ancestry) society and having to rely solely on immigration to replenish their numbers throughout the Portuguese empire.

During the course of the seventeenth century, the Dutch expelled the Portuguese from some of their colonies in South Asia and Oceania and thereby established their own settlements. However, the native Dutch did not immigrate to their colonial possession on the same scale as that of the Spanish and the Portuguese; rather, the Netherlands served as a conduit for foreign settlement for other European peoples (especially Germans and Scandinavians). The commercial hub of Amsterdam attracted droves of people from other parts of Europe, and in the midst of Dutch imperial expansion abroad, many of these people found themselves settling as merchants and soldiers in the service of the United Provinces (the Netherlands). As in the Portuguese case, high mortality rates among Dutch settlers made it necessary to replenish colonial populations with further immigration from the Netherlands, leading the Dutch East India Company to bring approximately 1 million people overseas from the seventeenth to the nineteenth centuries. Dutch settlements in the Americas, particularly along the Caribbean and in North America (New Amsterdam), also suffered from hard-pressed populations unable to replenish themselves from natural birth rates. However, many of these settlements fell to the English in the seventeenth century.

Emigration from the British Isles (England, Scotland, and Ireland) focused primarily on

settlement in the New World. English settlement of the West Indies and North America was similar to Portuguese and Dutch strategies (settlement was characterized by little regard for individual human life). When settlers died off from illness, warfare, or hardships, more were sent. English colonization of the New World occurred in tandem with the colonization of Ireland, which triggered an outflow of emigration from the English Celtic dominions of Ireland and Scotland. The task of populating an expanding British America depended to a great degree on the Scots and the Irish. However, English settlement of British America also relied on domestic population growth, with immigration to the New World seen as a release valve, particularly through indentured servitude and convict exile. Emigration for many was seen as a way to advance socially and economically in the New World, when issues of inheritance and dwindling land made it impossible to do so at home in England. However, gradual economic improvement domestically in the late seventeenth century led to a decrease in English immigration and a steady rise in Scottish and Irish settlement in British America.

French immigration abroad was limited only to those who had royal permission, which prevented a substantial number of French Protestants (Huguenots) from doing so. Economic prosperity in France also deterred people, except in small numbers, from going to the desolate and inhospitable fur trading outposts and colonies in Louisiana, Canada, and the Caribbean. A small group of planters and plantation owners embarked on overseas settlement, but not to the same degree as that of the Spanish, Portuguese, Dutch, and British. However, similar to those European nations, when their efforts to utilize European labor failed them, French colonizers found other sources of labor through the purchase of African slaves.

ENGLISH COLONIAL MODEL

English colonization of Ireland occurred simultaneously with that of British North America in the mid-seventeenth century. The Stuart dynasty had encouraged the formation of plantations in Ireland, particularly in Ulster, to Anglicize the recently subjugated Irish populace. Throughout the seventeenth century, an estimated 180,000 English migrants went to Ireland, in contrast with 116,000 to the Chesapeake. The term "plantation" initially referred to the settlement of people into a region. Eventually, the term was applied specifically to large agricultural estates.

As settlement into British America continued, many planters who settled in the West Indies and southern British America found the land ideal for planting particular cash crops such as tobacco, which created a handsome profit for the British Isles. In adapting the plantation model from Ireland to their new environment, these planters began to seek a similar subjugated labor pool, first with European indentured servants and later with imported African slaves.

"The Indians . . . Are Its Riches" — Depopulation of the Caribbean and Mesoamerica after 1492

The Spanish who first came to the Americas were looking for gold, silver, and other material wealth as well as trading opportunities. When they realized they had not reached Asia, the Spanish decided to make the best of the situation. Although some regions had precious metals, the European conquerors realized that other products offered opportunities for wealth. Agricultural products, such as tobacco and sugar, became important exports. However, the mining of gold and the growing and processing of sugar

THE TAINO SUFFER SMALLPOX

The Taino were the first Native Americans to come into contact with Europeans. As a result, they were the first to suffer from the diseases brought by the newcomers. In 1492 Columbus described the Taino as handsome and well-built people who were friendly and offered him assistance. Historians have estimated the number of Taino in the Caribbean in 1492 as half a million people. Spanish settlers forced the Taino to work as slaves, causing food shortages and malnutrition. In addition, the Spanish brought diseases that weakened the Taino, who had no resistance to European diseases. Smallpox first appeared on the island of Hispaniola (modern Haiti and the Dominican Republic) in 1518 or 1519. Most Europeans had been exposed as children, giving them an immunity to the disease that the indigenous did not have.

However, the Taino population was already in decline even before the smallpox epidemic. The disease merely accelerated the rate of decimation. In 1508 the Taino population was estimated at around 60,000 people. The 1510 census showed 33,523 Taino, and by 1514 only 26,000 Taino were left. When the smallpox first hit the Taino, their population had already dwindled to 18,000. By 1542, Spanish authorities estimated that only 2,000 Taino remained. After that time, they became virtually extinct as a distinct tribe.

—*Timothy J. Watts*

took much labor. This labor was initially provided by the Indians who lived in the Americas.

When Columbus made landfall in the Caribbean, he found a large population of indigenous people prepared to welcome the Spanish. The Taino, also known as the Arawak, had relatively small amounts of gold ornaments. An original group of 30 settlers was left behind after Columbus's initial voyage, and his return in 1493 found the settlement destroyed, as the Spanish had attempted to enslave the Taino, causing the Taino to attack the Spanish settlement. Subsequent voyages brought around 1,500 settlers, all male, to the island of Hispaniola (present-day Haiti and the Dominican Republic). Spanish incursions into the interior of the island discovered gold mines, and the natives were quickly put to

work. In addition, the natives were put to work in an agricultural capacity, with the expectation that the product of their labor would feed the colony. Unfortunately, the Taino had previously worked a subsistence lifestyle, which meant that they had only worked hard enough to feed themselves. The added work proved too much of a hardship for some and resulted in death. For the rest many refused to work, which meant that often there was not enough food to feed everyone. Pre-Columbian estimates of the Caribbean population range from 50,000 to several million. Whatever the original number, we do know that by 1542 there were only 2,000 Taino remaining, and by 1570 that number had shrunk to only 200. Spanish observers like Bartolome de las Casas, writing in the 1520s, blamed Spanish mistreatment for the decline of the indigenous population.

While work certainly had a major effect on the Caribbean population, disease also played a large factor. Although some historians speculate that the voyage that Columbus took in 1493 brought swine flu, the first major epidemic did not appear until 1518, when smallpox hit the Caribbean. The introduction of this virulent disease proved to be devastating to all of the Americas, as waves of the disease continued to spread over the next few centuries. After the initial outbreak in Hispaniola, the disease spread to Mexico and from there traveled down to Mesoamerica by the mid-1520s. This was not the first time that smallpox had appeared in the area, as it had accompanied the different traders who had passed by the area. Smallpox was not the only disease to hit Central America, although it was certainly the deadliest. A measles outbreak appeared in the early 1530s, followed by a pestilence in the 1540s that caused bleeding in the nose and eyes. One Spanish settler in Guatemala wrote that this particular pestilence killed three out of four natives there. Thirty years later another disease hit Central America, although historians are unclear as to the exact nature of the disease (whether it was typhus or the plague). It killed tens of thousands of the natives, possibly more. By 1570 the population that had once been between 2.25 million and 5 million had fallen to only 500,000. Five more pandemics hit the area before 1750, reducing the population still further.

NATIVE AMERICAN NATIONS PRIOR TO COLONIZATION

Spanish forced labor practices also contributed to the Native American population decline. In the first instance, Spanish conquistadors were rewarded with *encomiendas*, or grants of authority over certain populations of Indians. Under the terms of the *encomiendas*, the Spanish nobles received tribute and taxes from the Indians under their control. The Spanish were also able to force the Indians to work for them on projects such as building churches and palaces or working in their fields. In return the Spanish noble was expected to provide a clergyman to train the Native Americans in Christianity and to destroy the traces of native religions. In Mexico, Fernando Cortes limited the amount of work required from each Indian and ordered his conquistadors not to demand tribute in gold.

The use of *encomiendas* in the Caribbean proved to be a disaster for the Native Americans. Thousands were forced into slavery and mistreated. Those who resisted were executed, while others who broke the rules were tortured or maimed. Both women and men were forced to work in the fields and mines under very unhealthy conditions. The mortality rate was very high. The disruption to the Indian way of life helped to decrease the birthrate as well. Depopulation on the Caribbean islands followed, with a decline in the pool of workers. A similar pattern followed in Mexico despite the Crown's effort to avoid depopulation.

The spread of European diseases, however, may have been more important than forced labor in causing a population decline. Because Native Americans had no resistance to viruses carried by the Spanish, they suffered massive epidemics. In 1521 Cortes was able to capture Tenochtitlan partially because of a smallpox epidemic among the Aztec defenders. Epidemics of smallpox, measles, and other diseases had already devastated the Caribbean populations. Many of the diseases spread faster than the Spanish conquest, thanks to contact between different Native American peoples.

Estimates of the population of the Americas in 1492 vary greatly and range from 8.4 million to 112.5 million. Observations by Europeans are seldom accurate because they often arrived in a region after many Native Americans had already died.

Mississippian Mystery—Where Did the Moundbuilders Go?

The Mississippian Moundbuilders were the most advanced of North America's Native American societies. Between 600 and 1500 CE, different groups of Moundbuilders in the Mississippi River and Ohio River valleys built a large number of mounds. These structures apparently served ceremonial and political purposes as well as possibly serving as defensive centers. By the time French explorers came down the Mississippi in the 1600s, the Moundbuilders had disappeared. The reasons for their departure remain uncertain.

The Moundbuilders' society was based upon agriculture supplemented by hunting and gathering. In the early years, they domesticated plants native to eastern North America. Goosefoot, sunflower, and knotweed provided food and helped the peoples evolve into sedentary farmers. By 900, maize, beans, and squash had made their way from Mesoamerica into central and southeastern North America. The increased yields from these plants encouraged a population explosion and the creation of surplus food. Food surpluses allowed some individuals to devote their time to crafts and the creation of useful tools and exotic goods. Because these artisans no longer grew their own food, they depended on others for support. This situation helped lead to the creation of a hereditary chiefdom among the Moundbuilders. The chiefs were responsible for overseeing the distribution of food to all and the safe central storage of surplus supplies. The growing population led to the creation of cities that functioned as religious and political centers. The largest was Cahokia, with a population of about 15,000.

The growing power of chiefs apparently led to the creation of larger and more elaborate mounds. These consisted of packed earth and sand in a variety of shapes and sizes. The largest ones were topped with ceremonial buildings, either temples or homes for rulers. Most mounds were located around open plazas where the population could gather for religious or political ceremonies. These ceremonies included religious feasts, installations of new rulers, and funeral rites for important persons. Some mounds were used for the internment of important individuals. By 1200, rulers were buried with exotic goods, including copper tools and ornaments, carved stone and bone statues, pipes, and sea shells from as far away as the Gulf of Mexico.

Evidence indicates that Moundbuilder chiefs exerted great power over the individual groups or bands. They played important religious roles, controlled extensive trade networks, and decided upon alliances or war with neighboring groups. Although the Moundbuilders did not maintain long-distance trade routes, as did the Aztec and Maya, they did obtain status goods from great distances through hand-to-hand trade by neighboring bands. Their rulers used these exotic goods to ensure their favored position in Moundbuilder society. By remaining the exclusive consumer of exotic goods, the members of the elite made clear their favored status.

Archaeological evidence indicates that Moundbuilder culture began to decline by 1400. Fewer mounds were created, and the existing ones were less well maintained. The earlier practice of adding to existing mounds was discontinued. The populations of urban centers, such as Cahokia, declined. The small villages and hamlets that surrounded the cities also declined or disappeared. The reasons for this are unclear, but a number of theories have been suggested.

One possible reason is an increase in warfare after 1250. Many of the skeletons buried during this time period had embedded arrowheads or other marks of combat. Evidence indicates that new groups of hunter-gatherers were moving into the area from the north. These groups came into conflict with the sedentary Moundbuilders. Constant warfare may have driven Moundbuilders to migrate to new regions. Another source of warfare might have been conflict between different

Painting depicting the Cahokia Mounds settlement, built by the Moundbuilders in present-day Illinois, around 1150–1200 CE. (Cahokia Mounds State Historic Site, painting by William R. Iseminger)

groups of Moundbuilders themselves. The success of crops such as maize and beans in increasing the populations led to overpopulation. To support the additional people, Moundbuilders found it necessary to conquer new farmland, which they would have had to obtain from their neighbors. Or, internal disorder might have caused the decline. The gulf between rulers and ordinary people and the demands for labor and goods for the elites might have provoked uprisings.

Other theories about the decline of the Moundbuilders include ecological disasters. Deforestation and overuse of farmland may have led to erosion and declining harvests. With less food available, the population would have faced starvation or had to move to new regions.

One theory that seems to have been discredited is that disease might have caused the end of the Moundbuilders. Because Native Americans had little resistance to European diseases, many peoples were virtually wiped out by smallpox, measles, and other common diseases. Because archaeological evidence indicates that the Moundbuilders were in decline before 1492, disease apparently was not the primary reason for their disappearance. It may, however, have accelerated the process. A Spanish army led by Hernando De Soto marched through the Mississippi Valley between 1539 and 1543 and may well have spread diseases among the population.

Although Moundbuilder culture collapsed, many of the people probably migrated to other areas. Some archaeologists believe that Indian tribes such as the Osage and the Omaha may be descendants of the Moundbuilders.

Virgin Soil Epidemics in North America

When Europeans arrived in North America, they soon observed Native American populations getting sick and dying in great numbers. As time went on, horrendous epidemics and steep population declines occurred among Native Americans. Epidemics moved across North America beginning at first contact on the east coast and ending in the west in the nineteenth century. Apparently the illnesses began when Europeans first arrived, traveling across the land with casual contact between the existing societies. European settlers and explorers often came upon decimated or destroyed villages. In New England, for instance, Puritans found a great deal of cleared and previously settled land abandoned when they arrived.

The illnesses that the Native Americans were suffering from came from Europe and were called virgin soil epidemics because the populations at risk had no previous contact with these pathogens and therefore had not developed sufficient immunity to withstand the attacks. The precise diseases that seem to be new to Native America include bubonic plague, smallpox, measles, and influenza. Before European contact, Native Americans had suffered from tuberculosis, pneumonia, and possibly herpes, chicken pox, syphilis, and other viruses.

Scholars debate the significance of these epidemics and the resulting population losses. What caused such high mortality rates—as much as 90 percent in some communities, much higher than that of Europeans in the Black Death epidemics (50 percent) or among Civil War soldiers who contracted smallpox (38 percent)? How important was disease to the conquest of the New World? Scholarly debate centers on two hypotheses, one in which historians do not see disease playing a significant role in early postcontact period and the other suggesting that disease was quite significant. If the first hypothesis is correct, then the Native American cultures that Europeans first met probably accurately reflected precontact cultures; if the second hypothesis is correct, then precontact cultures were more complex.

While not all scholars agree on the extent of population reduction caused by these epidemics or even the size of the original population, multiple factors seem to be responsible for Native American susceptibility to European pathogens. The physical, economic, social, and political environments as well as poverty, social stress, weather, and hunger all contributed to the overwhelming mortality in Indian communities. One of the strongest factors was the general lack of nourishment (malnutrition), especially when people became too ill to plant corn or go hunting. Archaeologists have shown that many groups were terribly malnourished even before Europeans arrived. Health conditions had worsened in the years just prior to contact. Perhaps climate change was a factor; cold rainy weather confined people to their lodges, where they came in close contact with the ill, weakening their resistance. That may be why so many died when epidemics struck during the winter.

Another factor was the simultaneous infection of people by several diseases, which weakened their ability to recover. Since nearly everyone living in a community became ill at once, no one was left to cook, gather firewood and water, or nurse the ill.

Social factors also increased mortality rates. Individuals and societies react to the threat of epidemic death in different ways. Native Americans did not practice quarantine of the sick in pre-Columbian times, so diseases rapidly moved

from one person to another. Sometimes the healthy abandoned the sick in fear and despair and fled to other villages, bringing the illness with them. Sometimes the despair even led to suicide. For example, faced with a severe epidemic in 1738, several Cherokees killed themselves, sometimes killing their own families in their hopelessness.

War, exploitation, slavery, migration, and disease all had an impact on Native American populations. But it was probably successive epidemics that contributed the most to population loss. The repeated occurrences of the epidemics made recuperation very difficult. The epidemics caused tremendous social and cultural disruptions, but colonial policies also contributed to higher mortality rates among Native Americans because colonial leaders provided native people with little or no health care.

Some of the deadliest epidemics recorded by historians include those in 1616 and 1619, when bubonic or pneumonic plague swept coastal New England from Cape Cod to Maine, killing nine of every ten persons infected. Likewise, in the 1630s and 1640s smallpox raged throughout the St. Lawrence-Great Lakes region, killing half the Hurons and Iroquois. In the southeast in 1738, smallpox wiped out half the Cherokees and in 1759 half of the Catawbias. As Europeans moved onto the Plains and then to Louisiana diseases followed, killing large segments of the population living between the Missouri River and New Mexico. In the 1820s fever devastated four out of five people along the Columbia River. In 1837 smallpox returned and destroyed half the people on the Plains. These epidemics followed European explorers, traders, and settlers as they gradually moved west across the continent. As a result, the epidemics lasted for several hundred years in America.

Native peoples turned to their spiritual beliefs to cope with the stresses brought by these terrible illnesses. Some, such as the Cherokees, created special rituals such as the Itohnv (Smallpox Dance) that was used to ward off the illness. Cherokees and other Native American people often believed that evil spirits had sent the smallpox to punish them for breaking tribal laws or for not fulfilling spiritual obligations properly.

Before the arrival of Europeans, Native Americans had developed a cosmology that relied on a supernatural explanation for diseases. Bad fortune could be created by witches or wizards who were angry, and part of the so-called cure for diseases was the propitiation of evil spirits. These bad spirits could transform themselves into animals and then pursue humans to try to kill them. Native peoples continued to believe that proper personal behavior and consistent devotion to village ceremonies would ensure good health.

Although suffering enormous losses, native populations eventually did recover. As time went on, natives acquired immunities to the pathogens, but their population recovery was slow due to other factors resulting from encounters with Europeans: famine, warfare, stress, alcohol, and general social upheaval.

Disease also aided conquest in Mexico. When Hernan Cortes arrived, he brought smallpox and cholera as well as soldiers. Within a generation, the Mexican indigenous population declined by 95 percent. Though epidemics brought rapid demise to many communities of Native Americans, they did not monopolize the mortality. There were other deadly factors involved. Europeans and Americans killed countless American Indians through war, starvation, and neglect. Native American populations reached their lowest numbers by the end of the nineteenth century, but populations have continued to recover ever since as the result of better treatment and better health care.

Smallpox and Slavery— Demographic Catastrophe within the Americas

Historians agree that indigenous populations declined after the arrival of the Spanish in 1492. The exact amount of that decline is in question, thanks to the difficulty of estimating how many people lived in the Americas before 1491. Estimates range from 8.4 million to 112.5 million, although many of the higher estimates have been largely discounted. By 1650 the total had declined to around 5.6 million. The reasons for this decline center around Spanish mistreatment and slavery and the spread of European diseases.

When the first Spanish explorers arrived in the New World, their reasons for coming included economic exploitation. Columbus had expected to find an Asian civilization with which he could open trade relations. Instead he found stone-age peoples who apparently had little for trade. The Spanish were very interested, however, in the gold ornaments the native peoples wore. The Spanish quickly established themselves throughout the Caribbean, Mesoamerica, and South America as the ruling class, thanks to their superior weapons, tactics, and diseases.

The economic exploitation of the Native Americans took the form of forced labor. In many ways the Spanish continued a process that had begun under the native elite classes. Spanish rulers gave their followers grants of *encomienda* over certain territories. These were based upon native city-states that already existed. The Spanish grantees replaced the existing native elites or even cooperated with them to demand labor from the peasants who lived in the region. This labor was performed locally and included the production of agricultural products to support the Spanish rulers as well as labor for construction projects such as churches, palaces, and administrative buildings for the Spanish. In return for the Indians' labor, the Spanish rulers were to ensure that

the natives were good Christians. In practice, the grantees often hired their peasants' labor to other Spanish or even native nobles to work in their fields or perform other duties.

Forced labor by the Spanish was accompanied by outright slavery. In these cases Native Americans were forced into slavery to go where labor was needed. In many cases this meant the gold and silver mines, which might be located some distance from their homes. Both forced labor and slavery could be accompanied by cruelty from Spanish overseers. Bartolome de las Casas was one of the few who protested the exploitation of the natives and wrote about it. Beginning in 1514, las Casas wrote about the declining number of Indians in the Caribbean islands and how mistreatment by the Spanish was responsible. The "Black Legend" of Spanish genocide was born. It is unquestioned, however, that declining Native American populations caused the Spanish to import African slaves to work their plantations and other economic ventures in the Caribbean and the Americas.

The other major cause of the catastrophic decline in Native American populations is disease brought to the New World by Europeans. Because of their isolation from the rest of the world, Native Americans had little or no resistance to diseases common among Europeans and later among Africans. These diseases included smallpox, measles, whooping cough, and influenza; however, smallpox was among the deadliest of those transferred from the Old World. By the 1520s smallpox had already reached the present-day continental United States and had traveled as far inland as the Mississippi Valley and as far north as the Great Lakes. The appearance of this disease was quite traumatic to the indigenous Americans. Those who took sick were struck with high fevers, enormous amounts of pain, and of course the grotesque pustules that marked the skin. Often when smallpox hit a village, many would flee to other villages in order to escape the disease. However, rather than evading the sickness, this strategy only served to spread it to others. The first recorded instance of smallpox in British America was in the early 1630s among the Algonkins in Massachusetts. The pandemic erased entire villages and spread

NATIVE AMERICAN POPULATION DECLINE, 1500–1700

throughout New England and the Great Lakes region of French America, often traveling back and forth and returning to areas several times for the next 20 years. As a result, the Huron and Iroquois had a population loss of as much as 50 percent. For the next two centuries smallpox continued to ravage the natives, destroying populations in its wake. While some colonists were sad to see such devastation, others, particularly the British, were glad that smallpox saved them the trouble of forcing the natives off their land. Once an area had experienced a smallpox epidemic, it was easy for the British to then move in and claim the territory.

Of course, smallpox was not the only disease to be transferred into the New World, and sometimes these pandemics were unknowingly exacerbated by the natives themselves. Contacts between native peoples were common through trade and warfare. Individuals could become infected with diseases such as smallpox before they showed any symptoms. As a result, they might easily spread the infection before becoming sick and dying. Warfare could help spread the disease as well, thanks to native curiosity about the Europeans. Captives were prized and came into close contact with many warriors and leaders. Native treatments for diseases were ineffectual at best, while some treatments, such as sweat baths, helped to break down the body's resistance even further.

The effects of mistreatment and disease resulted in rapid declines of population. For example, Hispaniola (modern Haiti and Dominican Republic) may have had as many as 7 million people in 1492. The figures are based upon census figures by the Spanish, used to assign tribute levels among the people. By the middle of the sixteenth century the native population had nearly completely disappeared. Figures from other islands and the Americas are less complete, partially because of the effects of disease before the Europeans arrived to take possession of the lands. From New England to the tip of South America, large numbers of death from disease disrupted Native American cultures and made them less able to withstand European invasions.

Spanish Contact and Population Loss in the Marianas

The Mariana Islands consist of 15 Pacific islands located southeast of Japan and northeast of the Philippines. The island group forms an archipelago along a volcanic mountain range. The islands make up the most northern islands in Micronesia. Spanish contact in the Mariana Islands represents the first European encounter in the Pacific islands but is also exemplary of native mortality rates that would characterize many other populations throughout the Pacific and the Americas well through the nineteenth century. Spanish ships sailed throughout the Pacific exploring new lands in search of biblical islands and to Christianize the indigenous. Although the Spanish brought the Word of God, they also brought new diseases, wars, and misunderstandings that often reshaped every aspect of native life.

The early European explorers were sent to the Pacific with specific orders from King Charles II of Spain to spread Catholic faith and save the heathen souls of the natives. In 1668 half a dozen Jesuit missionaries founded the first Spanish mission at Agaña, Guam, escorted by their military platoon. Between the mission foundation and 1700, three disease epidemics were recorded by the governor, Jose Quiroga, in a letter to the Spanish authorities in 1720. The frequency of certain European diseases such as measles and influenza in Europe allowed those living there to gain considerable resistance to them. However, once these diseases were

One of the oldest known maps of the Mariana Islands, compiled from information provided by Jesuit missionaries, 1752. (Jupiterimages)

brought by ship to populations whose immune systems had never experienced them, the results were devastating. The Chomorro chief Hurao was quoted as saying, “If we had sicknesses we had remedies for them. But [Europeans] have brought us diseases but do not teach us the remedies.” Home repair, Spanish defensive work, and agriculture exacerbated the mortality rates with exhaustion.

The cultural reorganization caused by the mass mortality from disease as well as the mass migration of individuals to Guam caused a second wave of mass mortality. The islanders did not have any weapons comparable to those of the Spanish and could not defend themselves in battle. With many high-ranking people and family members dead, rituals, customs, and social structure changed. Often, the islanders were so opposed to Spanish and Catholic rule that

➤ SMALLPOX IN THE MARIANAS

The Europeans brought smallpox to the Marianas. Following infection through the respiratory tract, the diseased person experiences influenza-like symptoms. Smallpox lesions ulcerate, releasing virus down the throat and often suffocating the individual. Pustules form infectious scabs 8 to 14 days after the onset of symptoms. The disease plagued the Marianas in 1668. Two centuries later, smallpox killed 50 percent of Pohnpei in 1854 and Guam in 1856. By the end of the nineteenth century, diseases decimated the native population, and Spanish rulers brought in Carolinians to replace the lost population.

—Melissa Halverson

suicide and infanticide rates increased exponentially. The diseases lowered the number of fertile women and affected population rates for generations after. Estimations of population size in the Marianas at the time of the first mission were approximately 24,000 but declined to only 8,000 by 1700. Complications from the epidemic, changes to social structure, and military opposition lowered the population even more after this date. The Jesuit missionaries moved many islanders to centralized towns and converted many to abiding by Catholic family and religious structure. Many islanders were killed in attempts at protesting Spanish rule.

The natives of the Marianas suffered a common experience during Europe’s westward expansion. Through exploration and missionary undertakings, Europeans brought strange diseases and weapons with which the natives’ bodies and weapons could not compete. Although the total mortality caused by expanding European presence cannot be known, Native Americans throughout North and South America would endure many of the same hardships as the Mariana islanders.

■ Introduction: Envisioning the Environment

Environment affected not only how people lived but also how they thought or perceived themselves. Since times immemorial, humans enjoyed nature: vivid blue skies, broad horizons, fiery sunsets, deep canyons, and towering mountains. But human appreciation was limited to pristine nature and the natural world that was shaped by the human hand. In the Western world, societies embraced a tradition of viewing art as the mirror of nature. Thus, the great artists of the Renaissance sought to replicate the natural world in their paintings. Yet such inspirations were oftentimes restricted by religion that deemed nature an unworthy object of aesthetic appreciation and diverted art toward spiritual needs. In China, traditions portrayed nature as the manifestation of heaven's timeless pattern and order and described any natural imbalances (i.e., disasters) as humanity's fault. Thus, traditional Chinese views of nature called for respect for nature and finding balance with it. The Ming artists oftentimes portrayed nature as mystical landscapes with peaks shrouded in mist or clouds and serene valleys reflecting the natural balance of the world.

—Alexander Mikaberidze

Early European Studies of the Indian Environment

European accounts of the wonders of India date to the ancient world. Medieval travelers and missionaries added to the stock of information and legend, but European knowledge of the Indian environment grew after the establishment of

regular communication between Portugal and India following Vasco da Gama's voyage in 1498. Discussions of the Indian environment occur mainly in two genres of European works: travelers' accounts that include information about the natural environment to set the scene or establish India's geography, much of which was still legendary to Europeans, and collections dealing with Indian plants, usually in terms of their medicinal and economic value. Most of the early writings in the fifteenth and sixteenth centuries were the work of Italian and Portuguese travelers.

Most travelers focused on the human geography of India rather than the natural environment. What discussion there was focused on big features such as rivers and mountains. General comments about India's fertility and crops were also common. The traveler Lodovico Varthema of Bologna wrote an account of his journeys in the East while impersonating a Muslim in his *Itinerario* (1510). It became one of the most frequently printed and translated travel accounts of the sixteenth century, and it discusses some of the plant resources of India, including cinnamon and the sweet oranges of Ceylon, which he praised extravagantly. Like other travelers, Varthema focused on plants and animals of economic or medicinal value. (Plants that produced valuable commodities for Europeans, such as pepper, were appearing in the printed herbals, which were an expanding genre in the sixteenth century.) Varthema also describes the elephants and horses of India in a political context, as an element of the strength of Indian kings.

The earliest European studies of the environment of India from researchers based in India were physicians' investigations of Indian plants and their medical uses. The first scientific book printed in India was the Portuguese physician Garcia d'Orta's *Colloquies on the Herbs and Drugs of India* (1563). With a few scattered exceptions, the observations of European physicians on Indian botany and pharmacology before d'Orta had been unpublished and uncirculated, so his work marks the foundation of Indian botany as a European study. In addition to his own background in classical and Arabic medicine, d'Orta drew on the knowledge of Indian physicians and Persian and Chinese travelers he met while living in the Portuguese colony of Goa. His focus throughout is on medical use rather than botanical description. The Spanish court physician Juan Fragoso drew heavily but critically on d'Orta in his 1572 treatise on the fruits of the East Indies, but the principal vehicle for bringing d'Orta's work to Europe was the Portuguese physician Christavão da Costa's *Treatise on the Drugs and Medicines of the East Indies* (1578). Da Costa, who had traveled in the East himself and collected specimens, borrowed extensively from d'Orta's *Colloquies*, reorganized d'Orta's information, amplified his botanical descriptions, and added new material. Da Costa's work was widely circulated in Europe. More information on natural history was included in the unpublished correspondence of the Italian merchant Filippo Sassetti (1540–1588).

By the seventeenth century, a more diverse range of Europeans, including French, Dutch, and English travelers, was journeying to India, and accounts of their adventures and what they had seen became a popular genre in Europe. Although much of their focus was on the customs and buildings of the people of India, travelers such as Jan Huygen van Linschoten (1563–1611), a Dutchman in Portuguese service, also discussed the products, climate, and seasons of the country. Van Linschoten's *Itinerario* (1596) helped spark Dutch and English interest in India. The French physician to the court of the Mughal emperor Francois Bernier (1625–1688) concentrated on political and military analysis but also discussed the products of the country in his *Letter to Monsieur Colbert*. Bernier suggested that

➤ A SEVENTEENTH-CENTURY DUTCH CATALOG OF THE HORTICULTURE OF MALABAR

One of the largest works devoted to Indian botany was the 12-volume *Hortus Malabaricus* (*Malabar Garden*), 1678–1703, the fruit of a massive research project organized by the military commander of the Dutch East India Company (VOC) in Malabar on the southwestern coast of India. Hendrik Adriaan van Reede tot Drakenstein (1636–1691) organized hundreds of people from diverse cultures, including an Italian Catholic Carmelite missionary, Matthew of Saint Joseph, numerous Brahmins and Indian physicians, and members of the VOC with skill in medicine, chemistry, botany, and botanical illustration. Van Reede began the project with the hope of identifying profitable resources in the Malabar region for the company to exploit. The newly established Dutch station in Malabar was in a rivalry with the previously established station in Ceylon, and van Reede hoped to demonstrate the superiority of Malabar products over Ceylonese. The information on medical uses found in *Hortus Malabaricus* was mostly derived from local informants. The final work was the product of a complicated chain of linguistic tradition, from Indian languages through Portuguese and Dutch to the final product written in Latin for a Europe-wide audience, although few could afford the massive final product.

—William E. Burns

the country's combination of poverty with extreme fertility was caused by the Indian lack of the concept of private property.

The permanent establishment of European trading companies in India in the seventeenth century, preeminent among them England's East India Company, led to more systematic exploration of the Indian environment. The most voluminous study was the 12-volume *Hortus Malabaricus*, or *Malabar Garden*, a product of the Dutch East India Company. Nothing comparable was produced by the British East India Company in the seventeenth century; the major British contribution to the study of the Indian environment would not begin until the late eighteenth century.

The Tokugawa Garden

Japanese gardens derive their beauty from the combination and synthesis of various elements. There are no sculptured fountains, profusions of flowers, or even dynamic watercourses that are common in many European gardens. The compositional beauty of the Japanese garden is derived from a blending of several manifestations of material beauty that are met through various combinations of plants, rock, water, and sand.

The garden is also imparted significant symbolic beauty with a healthy mixture of Buddhist and Shinto elements that blend quietly with the natural art to establish the unique form of each setting.

Gardens have a long history in Japan. The custom originated in China and traveled to Japan around 1000 CE from China. In China, gardens were meant to be places of meditation and tranquility. However, Chinese gardens were not meant to have any order to them. They often had winding paths, man-made hills, and carefully placed locations of rocks, water, and bridges. The different natural elements were meant to inspire certain aesthetic sensations in the people who occupied them. When the Japanese began adopting gardens, they added order to their gardens and in some cases purpose. For example, the tea ceremony became important among the elite around the fourteenth century, and the garden became the site where the teahouses were built. In general, the goal of the garden was to appear natural but also aesthetically pleasing.

During the Edo period (1600–1868), there occurred a synthesis of garden art forms from previous periods. Compositional details were combined to create a synthetic whole that encompassed many different traditions. The Edo

garden often featured a large pond around which might be scattered a variety of different elements including miniature scenes from the 53 stages of the Tokaido highway that linked Edo (now Tokyo) with Kyoto and Osaka, views of Fuji, images of famous sites recounted in Japanese poetry, or other noted vistas. A winding stream was another common feature.

Edo gardens incorporated many Chinese elements. Often one found a pond in the shape of the Chinese character for heart (*kokoro*) accented by the sharp convolution of its shoreline. Other common elements included representations of the mythical Chinese island of Hōrai; *sanzonseki*, groupings of stones representing the three major Buddhas (Yakushi, Amida, and Shaka); Chinese-style embankments and bridges; Confucian-style towers; and representations of Chinese-style rice paddies and teahouses. All of these elements were merged into a harmonious design with natural scenes—greatly reduced in scale—of mountains, valleys, and rivers.

Kokoro ("Heart")

Many of these gardens were built for the homes of the daimyo (lord governors of provinces) not only in the administrative capital of Edo but also in their provincial seats. The use of a wide variety of motifs was common, especially in the larger gardens. Since the gardens were often constructed on low-lying flatland with very little topographical variation, the builders dug ponds, raised hills, and on many occasions employed the technique known as *shakkei* ("borrowed views"), whereby distant hills in the background would be integrated into the perspective of the garden, and introduced many other motifs into the design.

Some of the most famous of the Edo gardens, almost all of them originally designed as daimyo gardens, are found in Tokyo. They include the Korakuen, Hama Detached Palace, and Katsura Detached Palace gardens. Other famous Edo period gardens include the Korakuen in Okayama Prefecture, Ritsurin Park in Kagawa Prefecture, and the Shukkeien in Hiroshima Prefecture. The Korakuen garden is built around a large pond with a sharply indented shoreline surrounded by mounds representing mountains, small temples and shrines, ornamental bridges, miniature rice paddies, streams

➤ HOKUSAI AND UKIYO-E

Hokusai (1760–1849; given name Tokitaro) was an ukiyo-e painter, draftsman, illustrator, and print designer and one of the great masters of Japanese pictorial and landscape art. He is known for his highly individual idiosyncratic style combining Western and Chinese influences with elements drawn from a variety of native schools. As a child he showed a great interest in pictures and a talent for drawing. As a young man he eked out a living as a minor book illustrator, but his fame grew in the 1790s when he experimented with various new styles of ukiyo-e painting whereby he designed pictures that arose from his own vision rather than prevailing conventions.

By the early 1800s Hokusai had become a celebrity in the art world for his many styles of book illustrations. Among his greatest accomplishments were the *Hokusai manga* (Sketches by Hokusai), a series of picture books published in Nagoya during 1814–1834. His most famous series of landscape prints, *Fugaku sanjurokkei* (*Thirty-Six Views of Mount Fuji*), began to appear in the early 1830s. He published the equally famous *Fugaku*

A Shower Below the Summit, by Hokusai, from the series *Thirty-Six Views of Mount Fuji*, created between 1826 and 1833. (Library of Congress)

hyakkei (*100 Views of Mt. Fuji*) in 1834. His last major series of illustrations, *Hyakuninisshu uba ga etoki* (*Illustrations of the Hundred Poems*), appeared in the mid-1830s.

—Daniel A. Métraux

and waterfalls, and myriad cherry trees that bring thousands of visitors in April.

Since printing began to flourish early in the Edo period, texts with pictures of many of the more famous gardens were widely distributed. This phenomenon led in turn to the general popularization of the Edo garden throughout Japan and in the art of many of the leading artists of the eighteenth and early nineteenth centuries.

Nature in the Ming Imagination

The imaginative visions of nature that emerged during the Ming dynasty in China appeared in a variety of cultural expressions and artistic mediums. Whether in an excursion into the

countryside or in a painting of the stretching landscape, nature for the Ming represented the tradition of balance and harmony in an often complex and disturbing world.

The concept of nature in traditional Chinese thought stemmed from early beliefs of the essential link between Heaven and Earth. Heaven (*tian*), or the cosmos, represented the power that gave life to and ordered the world, or Earth. Nature was considered not only an extension of Heaven but also the manifestation of its timeless pattern and order. The deliberate movement of Heaven from day to day and from season to season confirmed its constancy. However, the natural world could be unpredictable, and so it was also believed that when unfavorable conditions for people to live and thrive were present on Earth, then the greater cosmic harmony was out of balance. According to early Chinese philosophers, the reasons for these imbalances in nature, or on Earth, were the fault of humankind, which was not living in harmony with the natural order of Heaven. This idea, now commonly

➤ **THIEN KUNG KAI WU (EXPLOITATION OF THE WORKS OF NATURE), 1637**

In contrast to the imaginative, idyllic significance ascribed to nature during the Ming was the realistic or utilitarian perspective toward nature as the source for food, clothing, shelter, and the necessities that sustain life and livelihood. The fact that nature implied natural resources was one that emerged time and again throughout premodern Chinese records. However, it was in the latter part of the Ming dynasty, when the scholar-official class began to write more from personal experience and knowledge, that more detailed accounts of how natural resources could be identified and used began to appear.

The three-part 18-chapter text with 122 illustrations *Thien Kung Kai Wu* (*Exploitation of the Works of Nature*) is widely considered the best example of premodern scholarship on the techniques and technologies used to process many of China's notable natural resources. Song Yingxing (1587–1666), the author of this encyclopedic text, intended the book to be a reference guide for the general understanding of how things were made, from agricultural products to mineral- and timber-based goods and various metals and gems. Song hoped that scholar-officials like himself or even members of the royal family might enjoy the concise topical entries, many of which were paired with intricate illustrations. Among the most engaging descriptions and visual narratives offered in the

(Ying-Hsing, Sung. *T'ien-Kung K'ai-Wu: Chinese Technology in the Seventeenth Century*, 1966)

text is the process of sericulture, or the stages of producing silk from silkworms.

—William Christopher Dalton

referred to by scholars as correlative cosmology, is at the heart of traditional Chinese views of nature. For the Ming, the origins of respect for nature and finding balance with it began with this legacy of early Chinese thought and belief.

Traditional philosophies were not the only influence on ideas about nature during the Ming. Increased population and urbanization over the course of the dynasty also played a significant role in shaping such concepts. Relative political stability allowed for an unprecedented growth of the population. Estimates of the early Ming population fluctuate around the figure of 60 million, while the increase in less than 250 years, at the end of the dynasty, possibly reached as many as 200 million. Infrastructure followed this trend as cities grew and expanded to accommodate

the burgeoning populations. Some larger cities, according to available data, are thought to have witnessed tenfold population increases. As cities and populations expanded, the economic and social aspects of everyday life grew more demanding. In order to slow down the pace of life and find a sense of balance, city folk sought the refuge of natural landscapes.

Travel for pleasure, or tourism, became quite popular, even among the common classes of society. Destinations for recreational travel featured local mountains, hills, rivers, and lakes. Often, the tranquility and scenery of natural surroundings were complemented by the availability of the medicinal resources that nature could provide. In many travel accounts, the fame of certain locales arose from the reputation

of some therapeutic fruit, fungus, root, tea, or spring water. Eventually, this kind of ecological tourism became embellished among the public, and the idea of the journey itself began to take prominence over the actual benefits that nature might provide.

For the elite classes, recreational travel also symbolized an essential experience but with a higher level of sophistication. While their destinations included natural sites of peace and rejuvenation, another sense of purpose usually pervaded their travels. Elite travel implied a sense of meaning, which stemmed from the traveler's appreciation of the philosophy, history, and literature of China's classic culture. Mountains and cliffs where great battles were fought or riverbanks where celebrated literary figures once composed poetic verse were the imaginative landscapes that dominated the elites' visions of nature while they traveled.

Similarly, the elite aesthetic of classical painting, inspired by well over 1,000 years of tradition by the time of the Ming, prefigured the imagination of nature. With light and impressionistic vistas of clouded peaks that descended majestically into lushly forested valleys, landscape paintings epitomized a serene longing for the natural balance of the world. Paintings of this kind were meant to accentuate the spirit of nature, not its realistic proportions. In parallel, designs on Ming ceramics, or china, followed this trend, and the serenity of nature was represented in portrayals of children or servants playing in a garden, floral patterns, or dragons and phoenixes sprawling through winding branches in blossom.

The elite quest to celebrate nature also influenced patronage of the emblematic Chinese garden. In these lushly decorated parks, the literary and aesthetic imaginations of cultured society were freed from the conventions of reality as well. Here, the elite could design the topography of their gardens in the images of classic landscape paintings. Looking to masterpieces as inspiration, they contoured their gardens with rocky outcrops, limpid ponds, and winding paths, all shaded and adorned by the flora of literary symbolism: bamboo and pine, peony and chrysanthemum, lotus and lily. The finest gardens could evoke wistful emotions or desires for

a simpler life, as evidenced in many poems of the period.

Similarly, elite men of scholarly or literary character built simple studios or huts in the countryside as retreats, where they could enjoy the serenity of groves of trees atop hills and scenic lookouts. The natural beauty of rustic settings offered valuable respite from the pressing affairs of politics, commerce, or family. There they could find an order to their thoughts as they strove to compose reflections as timeless as their natural surroundings. It is perhaps in the records and accounts that these intellectuals left behind that the Ming understanding of nature reflected its most basic and lasting character, which was the idea of its perpetual balance.

Western Ideas of Nature

Early modern Westerners understood the natural world, its role in a supernaturally governed universe, and their own relation to it in a variety of ways. Some approaches had classical and Christian roots, while others, such as the metaphor of nature as a vast machine, emerged during the scientific revolution.

One of the oldest conceptions of nature, with roots in the classical tradition of Greece and Rome, was that of the goddess Natura. This image was associated with fecundity and

➤ GEORGE SANDYS ON NATURE AS A PROTEUS

The English poet and colonial promoter George Sandys translated the Roman poet Ovid's *Metamorphoses*, a poem that many early modern people viewed as a treasury of ideas about nature, into English. Sandys's translation included extensive commentary on each book, often discussing the allegorical meanings of Ovid's stories. In his commentary on book 8, Sandys discussed the meaning of Proteus and his relation to nature:

"Proteus physically is taken for the First Matter, converting into all diversity of forms; which again resolve into their own original: and said to be the son of Neptune, because the operation and dispensation of Matter is exercised chiefly in liquid bodies. So is he taken for air (and therefore said to rest in a Cave, which is under the celestial concave) which ariseth from extenuated water: by whose secret operation both plants and living creatures are produced from the self same Matter, and the matter it self converted into Elements; which the Ancient expressed by Proteus his multiplicity of changes."

—William E. Burns

George Sandys, *Ovid's Metamorphosis Englished, Mythologiz'd and Represented in Figures* (Oxford, 1632), 297.

multiplicity and was connected to an image of the earth as a fertile womb from which living things and even minerals were formed and emerged. Natura was often represented as a nude woman, bearing signs of fertility such as supernumerary breasts or a basket full of ears of wheat. Users of this metaphor often utilized it to oppose what they saw as excessive exploitation of nature. Mining, for example, was sometimes viewed as an impious violation of the "womb of nature." Miners themselves claimed that the fertile earth would replenish that which they removed. However, Natura could also be described as decaying, growing old or senescent before the end of nature and the world together with the apocalypse. The birth of monsters or freaks was invoked as evidence of nature's decline.

This picture of decaying nature was opposed by those who emphasized intellectual and technological progress such as Francis Bacon, the English philosopher of the scientific revolution.

The natural universe could be treated as analogous to a human body and conversely the body as analogous to nature, the so-called microcosm/macrocosm theory. This idea also had ancient roots. The two levels of man and nature were linked as a network of correspondences so that the head or the heart in the body corresponded to the sun in the heavens. Naturally, this idea was easily adaptable to astrology, whereby each planet in the heavens could be seen as corresponding to a part of the body or organ that it governed. It was also used in medicine to indicate which plants corresponded to which ailments and thus could cure them.

The ultimate extension of the personification of nature was to treat the personification not merely as a metaphor but instead as actually existing. The idea of a Nature that actually performed tasks in the world could be traced to the medieval distinction between *natura naturans*, nature acting, and *natura naturata*, nature being acted upon. Natura naturata was the nature that people saw and perceived, while *natura naturans* was that which acted upon it to produce change. In the early modern period, those who believed in a self-acting natural universe, often influenced by alchemical or magical thinking, sometimes spoke of a "plastic spirit," intermediate between the created universe and God, that shaped the material universe as a potter shaped clay.

All of these views of nature as a deity or spirit, but particularly Natura, trailed a slightly suspect air of paganism. Natura naturans was sometimes described as God's subordinate or handmaid, but belief in such a powerful being lacking specifically Christian associations seemed idolatrous to many. Scientists like the Anglo-Irish chemist Robert Boyle, author of *A Free Enquiry into the Vulgarly Received Doctrine of Nature* (1686), thought that making nature an independent being derogated from God's omnipotence. The idea of a self-acting universe also seemed inconsistent with the mechanical philosophy of many early modern scientists such as Rene Descartes that reduced the workings of nature to matter and motion. Mechanical

philosophers defended themselves from charges of irreligion and asserted their superior piety by claiming that their systems took all agency from the material universe, vesting it solely in God. The overall tendency in the scientific revolution was away from metaphors that personified nature as a goddess or as a macrocosm to those that made it more mechanical, a vast machine or clock made by God, the “divine clockmaker.” Clockwork metaphors were advanced by the great interest that many early modern scientists had in clock making. Although the “clockwork universe” image is often associated with English scientist Isaac Newton and his system of mathematical physics, Newton himself never employed it because it seemed to leave too little room for divine action. Newton’s great rival the German philosopher Gottfried Wilhelm Leibniz, however, who had himself worked on creating a mechanical calculating engine, used clock metaphors often.

As the idea of investigating nature’s secrets grew more prominent in the scientific revolution, nature was often personified as the adversary of the natural investigator, someone whose secrets needed to be exposed, an image expressed most memorably, although not most typically, in Bacon’s call for “vexing” or tormenting nature by art to force her to reveal her secrets. Although this metaphor of conflict was often gendered as a conflict between a goddess and male investigators, it was not dependent on this gendering. Nature could also be portrayed as a male god, Pan, from the Greek word meaning “all.” Nature as Pan was represented as a being man above the waist and a goat below the waist, with a musical pipe with seven tubes representing the seven planets. The conflict between the investigator and nature was also expressed by the myth of the binding of the shape-changing sea god Proteus in ancient epics such as Homer’s *Odyssey*, whose heroes forced Proteus to reveal secrets. Pan and Proteus were linked, particularly in the alchemical literature, as embodiments of nature’s unity and multiplicity, respectively. Not only could conflicting metaphors for the relation of the investigator to the investigated be male, but metaphors gendering nature as female could also be used to advocate cooperation between nature and the scientific inquirer.

Another image of nature, which grew increasingly popular in the Enlightenment, was as a sovereign. Violation of the “laws of nature” was described as a rebellion against a sovereign. The idea of the “life according to nature” offered an alternative moral standard to the Christian idea of morality as a matter of divine commandment.

Constructing Catastrophe— Western Ideas of Natural Disasters

From 1450 to 1770 early modern European society, fraught by endemic warfare, episodes of famine, rampant disease, and frequent episodes of social and political chaos, developed particular notions of natural disasters associated with the greater instability of the times. Natural disasters, such as earthquakes, floods, and fires, were associated with apocalyptic cataclysms and millenarian eschatological rhetoric, or the idea that the world was at the “end times.” Given the religious fervor that characterized many early modern European societies of this period in the context of the Protestant Reformation and the Catholic Counter-Reformation, many of these themes resonated with the attempts to create a more pious and observant society and expunge “heresy” from their respective realms. Nonetheless, given the advances in the context of the Scientific Revolution and the skepticism fostered by the Enlightenment, much of this religious rhetoric was challenged by a more rational approach grounded in science and philosophical approaches and paradigms.

With the European discovery of the Americas in 1492 and the fragmentation of Christendom into competing denominations of Christianity in the sixteenth century, a sense of uncertainty pervaded throughout Europe as a sense of the unknown entered the public consciousness. Both the Catholic and the Protestant regions of

➤ GREAT LONDON FIRE OF 1666

The Great Fire of London of 1666 was a major fire that destroyed most of central London. For three days in early September, having initially begun in a bakery on Pudding Lane, the fire ravaged through the medieval city of London. Through the failure of the lord mayor in ordering the demolition of structures in an effort to quell the conflagration, the fire spread amid the proximity of the structures and buildings, creating a firestorm due to winds. In the aftermath of the fire, rampant fears of Catholic plots stemming from Rome, rumors of the event symbolizing divine retribution for war in the Netherlands, and widespread xenophobia against Catholics and the Dutch swept throughout London, resulting in violence and lynchings. Millenarian prophecies that the year 1666 would mark the “end times” were heeded with the great fire, giving credence to the already ubiquitous belief that the world was coming to an end.

—Abraham O. Mendoza

Europe developed particular ideas of what the existence of heresy (internally and externally) presented to their respective denominational ideologies. As a result of climatic changes at the end of the Little Ice Age, fluctuations in weather increased the amount of precipitation and resulting natural phenomena. Pestilence, famine, and warfare were associated with divine retribution for failure to cleanse society of religious deviants (Protestants or Catholics depending on which regions they happened to reside in where the other constituted a majority), witches, and Jews, among other enemies of the faith (particularly the “hated” Turk on the peripheries of the Habsburg realms). Commentators of the time, such as theological writers and religious leaders, preached about the coming end of the world, relating to the educated public as well as the illiterate masses of things to come. Thus, natural disasters were assumed to be the proof of the unfolding eschatological process.

Eschatology is a major theme within theology and philosophy focused on how events in human history were to develop in the context of the coming “end times.” As such, early modern European eschatology, as referenced in sermons,

tracts, broadsides, and other theological literature, placed great natural disasters as examples, drawn from the New Testament book of Revelation, as tangible proof of the end of the world and the return of Jesus Christ. The advent of printing technologies popularized these ideas to the literate educated public, while the illiterate masses were exposed to these ideas through religious sermons and itinerant preachers. The Four Horsemen of the Apocalypse, personified as Pestilence, War, Famine, and Death, which were prevalent problems in European society between 1450 to 1770, were presented in images and illustrations accessible to the public as further evidence of the end of the world. Furthermore, natural occurrences such as earthquakes, floods, and urban fires were attributed and associated with divine punishment, related to heresy or witchcraft. Demonology, the theological study of demons and their activities in tandem with witches (*maleficium*), was also related to the advent of any natural disaster in occurrence by both Catholics and Protestants of all stripes. This association of witchcraft to natural disasters and catastrophic occurrences was a prevalent theme throughout much of early modern Europe. This further led to the outbreak of witch-hunts and witch-crazes (which were witch-hunts on a vaster scale) in the sixteenth and seventeenth centuries, particularly in the denominationally and politically fractured Holy Roman Empire (Germany).

However, growing skepticism in educated circles in urban centers in the context of the Scientific Revolution and the Enlightenment and the late seventeenth and early eighteenth centuries shunned the “superstitious” and religious explanations for natural occurrences. In light of the scientific developments occurring throughout Europe, scholars and scientists questioned the theological explanations regarding what could be interpreted as natural processes through empirical research. Growing recognition by empiricists and philosophers that the natural world operated according to scientific principles that could be deciphered through research ignited a gradual paradigm change. However, a considerable portion of the European population, much of it illiterate and fervently religious in the late seventeenth and early eighteenth centuries, still

regarded such events as “acts of God” or the work of the “devil” in the context of the coming end of the world.

Representing Europe's Crisis of the Seventeenth Century

The crisis of the seventeenth century, popularized by English historian Hugh Trevor-Roper, remains a controversial point among scholars. For many historians, the period of instability and disorder was a paradox. Triggered by the economic and political decline of the Spanish Habsburgs and its effects on the rest of Europe, the crisis is represented in the art and culture most strikingly by its absence. The historiographical debate among historians, such as Theodore K. Rabb and Simon Schama, regarding whether in fact there was a crisis or if it was limited to certain countries continues. While there was no doubt in the minds of Spanish artists and intellectuals that imperial Spain was going through a protracted economic and political decline relative to the rise of France and England, Spanish culture nonetheless experienced a golden age characterized by exquisite paintings, inspired theater, and brilliant literature. Elsewhere in Europe in the midst of the Thirty Years' War (1618–1648), the English Civil War (1642–1646; 1648–1651), the Revolt of the Dutch Republic (1555–1648), and the Fronde revolts in France (1648–1653), the arts continued to flourish unhampered and perhaps motivated by such instability. The resurgence of the Catholic Church in the Counter-Reformation inspired the Baroque style in art and music. The small states in the Holy Roman Empire, while clashing with the Catholic Habsburgs in the midst of the

Thirty Years' War, still found the time to patronize and enjoy the fruits of seventeenth-century culture. The seventeenth-century crisis, while devastating for Europe, was a remarkable time for European cultural forms.

Habsburg Spain experienced a protracted decline from the death of Philip II (1598) to the end of the reign of Carlos II (1700) while simultaneously enjoying a veritable golden age in the arts. Spanish art flourished in terms of painting, theater, and literature. During the reign of Philip IV (1621–1640), Diego Rodríguez de Silva y Velázquez (1599–1660) was Spain's most important seventeenth-century painter, representative of the flourishing of Spanish artists of the period. The work *Las Meninas* (1656), regarded as Velázquez's masterpiece, is a group portrait scene and self-portrait. Many of these paintings emphasized the beauty and grace of the Spanish royal family and the aristocracy, celebrating them in spite of the ubiquitous decadence of their state and society. Spanish theater also contributed to the richness of the nation's culture during the seventeenth century. Among the main contributors to its glory is playwright Felix Lope de Vega (1562–1635). He wrote an estimated 1,800 plays and a large amount of poetry inspired by his many love affairs. Vega invested much time on his comedies (*comedia*), making it a notable national genre in drama. Many of his plays reflected the social and economic problems prevalent in Spanish society in its accelerated state of decline. Spanish author Miguel de Cervantes (1547–1616) published *Don Quixote* in 1605, among the great classics in world literature to this day. This work famously satirizes the anachronistic social values of the Spanish aristocracy in a rapidly changing world where such values have no function.

The Catholic Church experienced a vast revival in its influence against the advances made in the previous generation by Protestantism in its Lutheran and Calvinist forms. The artists and musicians of the Baroque movement, prevalent in Catholic Europe, attempted to trigger the devotion of Catholics through an intense display in ornate artistic and musical styles. In Catholic Spain, France, Austria, Italy, and southern Germany, the Baroque made significant inroads in painting, architecture, and music. Emphasizing

> LAS MENINAS, 1656

Diego Velazquez's *Las Meninas* is a masterpiece of the Golden Age of Spanish art. *Las Meninas*, meaning "maids of honor" in the Spanish court, refers to the ladies-in-waiting portrayed in the painting. Velazquez's study depicts the Infanta Margarita, the daughter of King Philip IV of Spain, surrounded by two ladies-in-waiting, a dwarf, a jester, a dog, and Velazquez himself painting. In the mirror above the head of the Infanta is the royal couple, and a chamberlain is in the doorway to the right of her. The point of view of the picture is approximately that of the royals, apparently having their portraits painted. This picture represents the artistic focus on the royal family, which sought to emphasize the glory of the monarchy in an age of decline in the midst of the crisis of the seventeenth century.

(The Gallery Collection/Corbis)

the ornate, the elaborate, and the passion of the Catholic faith, this genre also contrasted heavily with Renaissance Classicism, which had emphasized order and harmony. Notable Baroque artists, such as the Spanish painter El Greco (1541–1614) and the German composer Johann Sebastian Bach (1685–1750), utilized their skills in creating work that represented the rebirth of Catholic devotion in the pursuit of winning back adherents to the faith. The previous period, wracked by wars of religion and denominational schisms, had subsequently been followed by one in which high culture would play a significant role in inspiring the Catholic masses.

In Protestant Europe, particularly England, the Netherlands, and northern Germany, the arts flourished thanks to the newfound economic and political expansion of these regions. While they did experience widespread war and severe economic fluctuations in the midst of the crisis of the seventeenth century, they

nevertheless became renowned for their art and high culture. The Stuarts in England, the stadtholders in the Dutch Republic, and various German princes illustrated their appreciation of the arts, as was fashionable in other parts of Europe, by furnishing their palaces and courts with vast amounts of paintings. German painters Albrecht Dürer (1471–1528) and Hans Holbein the Younger (c. 1497–1543), and Flemish painter Pieter Brueghel the Elder (c. 1525–1569) all made their living painting for the northern Protestant courts. Many of these paintings exemplified the current themes of this era, namely the glory of political leaders and military victories and the defeat of their Catholic enemies. England and Dutch economic growth was reflected in an expansive investment in such luxuries that they could afford, while in small German principalities it taxed many an overburdened prince's finances.

Society and Culture

Most of the world experienced a dramatic change in social apparatus during the early modern period. The advancement of agricultural and naval technologies made possible the subsequent rise in global trade, changing the way many societies interacted both domestically and internationally. Protoindustrial technologies grew. Centralization of power in Europe and Asia restructured social hierarchies across many cultures. Quite often new technological, economic, and political realities restructured societies, altering relationships among rulers, elites, and commoners. As one would expect, the impact of early modern technological and political changes varied widely. Some European societies entered into dynamic periods of rapid change, some stable societies such as China began a slow transition, and the introduction of unfamiliar pathogens devastated vulnerable societies such as those in the Americas. Although the indigenous populations of the Americas provide the most dramatic example, living conditions in rapidly expanding densely populated cities presented public health problems in many areas.

Urbanization accelerated in many areas but perhaps most dramatically in Europe. Towns were not new phenomena in the early modern period, but their size and importance as marketing and financial centers grew as the medieval period ended. Europeans began a slow transition to market-based economic organization. Europe gradually entered the world markets. By the end of the fifteenth century the Portuguese had discovered a sea route to India, finding a way to reach Asia without going over the Muslim-dominated land routes. As the spices and other products began to arrive from Asia and the gold and silver poured in from the Americas, the towns and cities in Europe grew in prominence as their populations rose in response to all of the new economic activity. Despite the growth in importance of these towns, they tended to be more specialized and remained dependent upon the countryside villages for necessities such as food. The close proximity of the villages to the towns facilitated this relationship, but as the market-based economic system developed further, it became more difficult for people in the countryside to survive on subsistence-level production.

In order to ensure sufficient food for their populations, many cities maintained fields and orchards. Inhabitants of cities in places such as Flanders, England, and Italy often left their urban jobs during the harvest and planting seasons in order to work in the fields. Many western European towns retained an agricultural identity despite their urban natures. Fields and orchards were in close proximity, pigs roamed the streets freely, and the streets were often muddy and filled with trash.

Many western European towns retained an agricultural identity despite their urban natures. Fields and orchards were in close proximity, pigs roamed the streets freely, and the streets were often muddy and filled with trash.

Streets in the city of Frankfurt had to be covered with wood shavings and hay before fairs could be held. In 1746 Venice finally prohibited keeping wine in the city. On the other hand, the countryside also had

its share of “urban” tradesmen, such as blacksmiths and artisans. Villages in less urbanized societies, such as in Russia, China, and India, tended to be much more self-sufficient out of sheer necessity. The Russian Law Code of 1649 that made serfdom a permanent status for millions of peasants ensured that the state would remain mostly agricultural in nature. This law restricted these serfs from moving to any other trade, keeping the balance of

the population rather stagnant. Russian cities and towns lost social mobility. These Russian urban areas were already small and few in number; even Moscow only had 40,000 houses in 1636. Thus, the manorial estates had to be self-sufficient and establish many of their industries for the benefit of the serfs and lords. The villages of China and India were not quite as self-sufficient. Peasants could produce most of their own products but did depend on the city for goods such as iron and silk.

Islamic towns tended to have unique characteristics, no matter their location. Most were large, and they were normally remote from one another. The Muslim prohibition against multistory houses (considered prideful) ensured that structures were generally low and clustered together. Mecca and Cairo were two exceptions to this rule. The streets were not paved even in the seventeenth century, which left them muddy in the winter and dusty in the summer. In addition, the streets were extremely narrow and winding, which often left them obstructed with traffic. Despite the disorderly streets, some planning was evident in the towns and cities. The mosque was the center of every town and was surrounded by markets and warehouses. From there the various industries were normally organized in concentric circles and were distanced from the mosque according to their perceived cleanliness or lack thereof. For instance, incense and perfume merchants were usually located closest to the mosque, while blacksmiths and those who managed livestock or beasts of burden established themselves at the outskirts. People from the countryside who sold meat, wood, and crops that they grew in their fields were located by the gates, even farther from the central mosque. Islamic towns also tended to be organized by religious adherence; nearly every town had Jewish and Christian districts.

Chinese cities shared similarities with those in Europe and the Islamic world, but some—Beijing, for instance—also had many unique, purely Chinese aspects. Beijing was surrounded by walls that had at one time been used for security but after 1644 enabled the dynasty to collect tolls and monitor the comings and goings of citizens. Before the mid-sixteenth century those walls had been made of clay, but the Ming had rebuilt them with brick during a campaign to strengthen defense. Beijing was surrounded by suburbs and was itself divided into two main sections: the old town and the new town. The Ming dynasty built the new

town to solve the problem of overcrowding in the old section. However, after the establishment of the Qing dynasty in 1644, Manchus resided in the old town, pushing the ethnically Chinese to the southern section.

The old and new towns shared many similarities. They were both built on a checkerboard plan and tended to be extremely congested. The houses were low, even those of the wealthy. The houses of the elite usually had five or six apartments spread apart on a single level and joined by a common courtyard. Public displays of wealth were considered poor form. Servants' quarters occupied the front, usually behind a gate. The homes of the wealthy shared the streets with artisans' booths and shops, which were intermingled with the gated living quarters. The Imperial Palace was at the center of the old town. Surrounded by layers of thick walls, the area of the palace compound measured over half a mile (.8 kilometers) long and 853 yards (780 meters) wide. The inner sanctum, known as the Forbidden City, housed the emperor, his wife, concubines, children, eunuchs, and guards. The Qing built this structure over the ruins of the old Ming palace as a formidable reminder of their new power.

As time passed, the political importance of the kings and emperors grew as they either centralized their power or, as in the case of China, one failing dynasty (the Ming) was replaced with another more dynamic one (the Qing). Rulers became the epicenter of society and commerce, driving the growth of cities. In Europe this was a significant change from the medieval era of itinerant monarchs moving throughout their kingdoms, dispensing justice, settling disputes, and in so doing limiting the power of regional lords. The new capital city, where the king resided, became a center of trade, creating national markets and drawing a large number of people. It was generally the largest city of the realm. As power centralized in the person of the king, there was less of a need for the king to appear in person. A monarch could remain in one city for most of the year. This phenomenon was not limited solely to Europe. In India the residence of the prince or sultan completely dominated the capital city. However, unlike Europe, in India the capitals tended to shift according to the whims of the monarch. For instance, the capital of Bengal changed from Rajinahal (1592) to Dacca (1608) and then to Murshihad (1704). The court remained the center of economic activity in the city where it was located. The members of the court depended on the prince for their livelihood, just as many city dwellers depended on supplying the court with food and other items as their own source of income. Every time the city lost its royal resident, most people would follow the prince, and the depleted city would lose its status as a major city.

The situation was similar in the Mughal empire. The city of Agra was the original capital city of the empire until Shah Jahan decided to move his court to

Delhi in 1638. The Mughal capital remained in Delhi as long as the sultan remained in the city. Aurangzeb traveled to Kashmir in 1663, and almost the entire city of Delhi followed after. A French doctor who

Every time the city lost its royal resident, most people would follow the prince, and the depleted city would lose its status as a major city.

witnessed the expedition estimated the number of the group to be several hundred thousand. This was not evident in Europe. When the king left the city the court followed, but the city remained functioning and populous. In Japan this system came into being with the advent of the Tokugawa Shogunate, imposed by the shogun himself. The daimyo, or the noble class, were required to establish a residence in the city of Edo (present-day Tokyo) and reside there at least six months a year. The other six months the daimyo were obligated to leave at least one family member in residence in order to prevent any rebellions. In this case proximity to the shogun was not optional, and the nobles were more itinerant than the ruler.

The cities of colonial America did not reach the size and importance of the older cities of Europe and Asia. Paris and Naples had roughly 300,000 citizens in the seventeenth century, but Rio de Janeiro only reached a population of 100,000 in 1800 and was one of the largest cities in the Americas. One reason for this may have been the absence of royalty from the colonies. Until 1807 when King João VI of Portugal sailed to Brazil in order to escape Napoleon's army, no European monarch had ever set foot in one of his or her overseas colonies. Therefore, people who depended on the monarch for favors and livelihood remained in the metropolis. Another reason for the small size of colonial cities arises from the very nature of the colonies themselves and the products they produced. The purpose of the colonies was not to become bustling centers of commerce but rather to provide raw goods to the mother country for manufacturing. Therefore, the plantations, mines, and wharves were the centers of economic activity in the Americas, not the cities themselves. The wealthy elite lived in the rural areas on or near the plantations and mines rather than in cities. Many of the haciendas and plantations actually took the role of villages, operating as autonomous entities not dependent on any cities or towns, as villages in Europe and Asia tended to be. Despite this, in many ways the cities of the Americas were miniature replicas of their European counterparts. Masons and other artisans arrived from Europe in order to replicate the stone buildings and other edifices of Lisbon, Madrid, Paris, or London. While they did not have the wealth or opulence of the European metropolitan cities, cities like Mexico City or Rio de Janeiro had characteristics that symbolized European distinction, reminding the indigenous people that a new power structure was present.

As is true in every society, alterations in the economic structures compelled changes in social organization. Each social class in medieval European society had its own place, resulting in extensive stratification. With the new overseas trade, many merchants became wealthy, achieving higher status at court even as the income from land, upon which the traditional nobility depended, became increasingly uncertain. Intermarriage between the nobility and bourgeoisie merchants became increasingly common. Taxes and the sale of monopolies to overseas traders were enriching kings, promoting centralization of monarchical power. The nobility became increasingly reliant on the goodwill of the monarch. With professionalization of the military, they were no longer the realm's warrior class, although most officers tended to be of aristocratic

birth. Nevertheless, the nobility needed the monarch's friendship and favor to prosper. Nobles did not easily surrender their medieval power, but the increasingly close relationship between monarchs and the merchant adventurers kept the power of the nobility in check.

Because the king and most of the nobles remained in the metropolis, the wealthy planters and merchants became the colonial elite. The lack of a substantial number of eligible Portuguese and Spanish bachelors meant that the normally strict social standards for marriage were relaxed. In Portuguese and Spanish America, even standards of color were sometimes relaxed. With enough money a person could purchase a Certificate of Whiteness, which established that the recipient would be considered white by all institutions no matter their skin color. This was especially advantageous for those elites whose children were mulatto or mestizo, who otherwise could not have been eligible to inherit all lands and titles. The British American colonies had no formal provisions for racial mobility; the colonists were more interested in pushing the natives away from their societies than in attempting integration.

In India many of the Mughals strove for social integration. Babur, the first Mughal emperor, invaded India from Central Asia in the early sixteenth century. A Muslim, he was both an ethnic and a religious minority. The only way he and his successors could rule a people where Hinduism was the religion of the majority was to find a way to ensure the population's loyalty while not infringing on their everyday lives. His grandson, Akbar, was able to achieve this

balance and solidified the sovereignty of the Mughals. Akbar picked all of his 800 wives from families who had served as local rulers and/or governors before the arrival of the Mughals. He ensured the loyalty of the local elites by raising their status in relation to their daughters' marriages. In addition, those daughters could serve as hostages to ensure their families' loyalty. Akbar also employed the system

Akbar picked all of his 800 wives from families who had served as local rulers and/or governors before the arrival of the Mughals. He ensured the loyalty of the local elites by raising their status in relation to their daughters' marriages.

of the *jizya*, or nonbeliever tax, that provided income for the government while allowing Hindus to retain their religions. As a result, he was able to centralize the Mughal power to the point that the entire city that housed the emperor became completely dependent on him and his favors.

In East Asia similar trends were occurring. The Qing dynasty was able to consolidate Manchu power in China and ensure their success for the next 250 years. The dynasty's founder, Nurhaci (1559–1626), prohibited intermarriage and too-close associations between Chinese and Manchus, although these proscriptions were sometimes breached. He also ordered that Chinese men signal their loyalty to the Manchu by adopting the Manchu hairstyle, shaving the hair on the front of their heads and wearing the back in a long braid. Chinese men resented the requirement and protested fiercely, but the Qing held firmly to the policy, suppressing resisters and enforcing the hairstyle requirement. Nevertheless the Manchu, never constituting more than 2 percent of

the Chinese population, remained in power more through collaboration than by force. The Qing adopted many of the Chinese customs and habits, supporting a very conservative Confucian worldview.

All considered, perhaps the greatest cultural impact of the European contact with East Asia was most evident in sixteenth-century Japan. In the fifteenth century Japan went through a period known as the Warring States Era. While the emperor was still the nominal head of the government, the true power lay with the regional lords, who were warring with each other. The arrival of the Portuguese (who introduced firearms) changed the situation. Oda Nobunaga, a territorial lord (called a daimyo), used firearms to defeat his neighbors. By the time he died in 1582, he had succeeded in conquering a third of the daimyo in Japan. Nobunaga's successor, Toyotomi Hideyoshi, completed the unification. While he never achieved the rank of shogun, he was named *kampaku* ("regent"). With this new power, he set about ensuring that he would be able to retain this power. Namely, he had to ensure that the samurai, or the warrior class, would maintain their monopoly on military matters by confiscating all weapons from the peasants in 1588 and having them melted down. He had also had all Christian missionaries exiled from Kyushu the year before. Christianity posed a threat to his power in the fact that it was the religion of the foreign kings and a foreign god, but it had also brought him the power to overtake his neighbors, and he was not anxious to see that occur again. His feelings toward the Christians continued into the Tokugawa dynasty, which started in 1603 and resulted in the banning of Christianity altogether as well as the closing of Japanese borders by the 1630s. In this case the European influence resulted in the centralization of power under the shogun, which brought peace to Japan after a century of war. However, it also guaranteed that their own influence would be almost nonexistent until the nineteenth century.

Innovations of the early modern period transformed societies all over the world. The advancement in both naval and military technology in this period allowed people to move about the world with more ease than ever but altered the balance of power. Empires like the Ottomans, Mughals, and Habsburgs benefited, changing societies not only in the lands they conquered but at home as well. In addition, the new economic forces that resulted from this movement pushed some societies even further into change.

—Monique Vallance

■ Introduction: Village and Town Life—Traditions and Innovations

Towns and villages existed for many reasons in the first global age. Some were agricultural, oriented toward food production for local consumption. Some were oriented toward the production of agricultural goods for export, as were the villages of the wine-growing districts in France. Food production for export also dominated coastal fishing villages. Others were dominated by mining or industry, such as porcelain in China and Japan or weaving in Lancashire in England. Some villages and towns were dominated by a single governmental, military, religious, or educational institution or by trading companies, like the Dutch East India Company's town of Batavia or Albany, the center of the Dutch fur trade in North America. Towns like Qom in Persia and Compostela in Spain were important pilgrimage sites due to their shrines. Some villages were even dependent on criminal activity, such as smuggling.

Expansion and technological and economic change in the first global era led to many changes in everyday life in town, village, and rural settings. The expansion of Western Christian and Islamic civilizations brought with it new institutions such as churches, mosques, and religious courts. The growth of global trade also affected urban development, with the creation of cities to serve as entrepôts. Boom towns were created by economic changes, while other towns languished when their chief industries became economically obsolescent.

Towns and villages were governed by custom and formal law. States were represented sometimes by magistrates from out of the district and sometimes by local elites. Lineage groups played an important role in Chinese communities, as did religious confraternities in the Spanish empire. The idea that cities were corporations with distinct legal personalities, a legacy of classical Greek and Roman civilization, vastly affected the development of urban life in Europe and its colonial empires. Western cities, towns, and even some villages retained a degree of legal independence unmatched by their

equivalents elsewhere in the world. This can be seen in the development of unique civic institutions, such as the town meetings of the self-governing communities of Puritan New England. The Spanish and Portuguese model of village and town life was also exported to their American possessions. Although Islamic cities lacked legal personality, the urban elite had a distinct identity sometimes in tension with that of the state as *ulama*, the learned Muslim scholars to whom many ordinary Muslims looked for guidance. The Ottomans more than other Muslim rulers tried to incorporate the *ulama* into the bureaucracy of the state, but they still remained independent sources of authority in many Ottoman cities.

Although the general tendency in the early modern era, as throughout human history, was for a greater proportion of people to live in towns, villages, and cities than to be nomads or live in isolated settings, not all changes in the early modern era were in the direction of greater urbanization and population concentration. The introduction of the horse to Native Americans actually resulted in deconcentration of Native American populations, as tribes abandoned agricultural villages in favor of a buffalo-hunting lifestyle enabled by horses.

—William E. Burns

Life in the Village and the State under the Great African Empires—Songhai and Kanem-Bornu

During the sixteenth century, the great African empires of Songhai and Kanem-Bornu reached their apex politically, socially, and economically. While the ruling classes of the two empires were privileged, the majority of inhabitants led hardscrabble lives unconcerned with the notions of conquering land and consolidating power that consumed their leaders. Although there were many similarities between life in the two imperial neighbors, there also were substantial differences.

➤ *TARIKH AL-SUDAN*

The *Tarikh al-sudan* (*History of the Sudan*) is the Arabic chronicle of the Songhai empire written by Abd al-Rahman al-Sadi (b. 1594), a bureaucrat and scholar living in seventeenth-century Timbuktu. Much of what we know about the history of the Songhai empire and its major cities of Gao (administrative capital), Timbuktu (scholarly center), and Jenne (trading hub) comes from this chronicle. The *Tarikh* was written more than a half century after the fall of Songhai to invading Moroccan forces in 1591. The 35-chapter work includes the history of several centuries of early Songhai dynasties as well as the Mali empire, biographies and obituaries of notable personalities, noteworthy events, descriptions of major Songhai cities and their environs, and, most importantly, a history of the rise and fall of the Songhai empire and the resultant internal and external difficulties that the Moroccans encountered in administering the conquered lands. While other chronicles such as the *Tarikh al-fattash* covered a similar subject matter, al-Sadi's work is the standard by which other early West African chronicles are measured. The *Tarikh al-sudan* was translated into French at the turn of the twentieth century and was translated into English a century later in 1999.

—Brent D. Singleton

Geographically, Songhai and Kanem-Bornu were centered in the Sahel (semiarid savanna) region of west and central Africa, respectively, and each extended north into the trade and salt-mining settlements of the Sahara. This region had long been fertile for the spread of Islam, and Songhai and Kanem-Bornu were both undergoing Islamization during this period. Many inhabitants of the empires were at least nominal Muslims, often blending Islam with traditional beliefs. Under these expanding empires, both Muslims and non-Muslims alike were being pressed to conform to the more orthodox beliefs and practices of Islam.

Both societies had centralized governments and were highly stratified socially. In Songhai, the *askiyas* (kings) and the Songhai elite benefited from all other elements of society who were in some form or fashion subjugated to the state. For instance, the Sorko, an indigenous

people of the Niger Bend region, were in a state of semienslavement to the *askiyas* and were required to provide transportation and services in the river-based economy. In Kanem-Bornu the *mai* (king) owned all of the lands, and these were divided into fiefdoms ruled over by the royal family and other nobles living in the capital. Using subordinates and local leaders to run daily affairs, each fief ruler was responsible for collecting taxes and raising troops in time of war. The society was broken down into royalty, nobles, and commoners, with each of these groups having several further levels of stratification.

Songhai was economically and politically dependent on the Middle Niger Valley river culture. Its major cities, Jenne, Gao, and Timbuktu, were in close proximity to the river, which favored commerce, communication, and agriculture. However, a large proportion of citizens in both empires lived in relatively small villages. In Kanem-Bornu the villages were made up of family compounds, which were groups of round structures constructed of mud brick supporting conical thatched roofs. Families usually engaged in a common trade and banded together with other families of the same trade group.

Ethnicity played a major factor in both empires. The Songhai conception of ethnicity was more or less delineated prior to the sixteenth century. All non-Songhai peoples were seen as foreign, yet they were incorporated into the empire based upon their value to the ruling classes. For instance, the nomadic Tuareg, Fulani, and desert tribes often provided livestock, while sedentary groups such as the Mande and Hausa farmed, fished, or traded. On the other hand, Kanem-Bornu was dominated by the Kanuri people, a distinction that was dynamic during this period. As groups were incorporated into Kanem-Bornu, they were pressed to become Kanuri through adopting the culture and language as well as Islam (if not already Muslim) and intermarrying with the Kanuri.

Slavery was ubiquitous in both Kanem-Bornu and Songhai whether in service to the state, villages, families, or individuals. Being a slave did not always preclude one from being born into or attaining a high social status or position. Slaves would be found in nearly every class of society in Kanem-Bornu and often owned slaves

themselves. However, the vast majority of slaves in Kanem-Bornu were engaged in menial farm or household work. In Songhai, captives from the nearly ceaseless military campaigns were often enslaved in the cities of the empire or on large agricultural farms, which produced rice and grains. Both trade in and work provided by slaves was integral to the empire's economy. Nonslave commoners who were not directly dominated by the Songhai state or elites were indirectly affected by high taxation on agriculture, trading, and salt mining as well as fear of enslavement, conscription into the military, or both.

Ottoman Expansionism in North Africa during the First Global Age

Ottoman engagement in North Africa began in 1487, when the Ottoman sultan Bayezid sent ships into the western Mediterranean. He aimed to assist Muslim refugees who were fleeing from Granada (the last Islamic polity in the Iberian Peninsula) to the coast of northwestern Africa (which is the region known as the Maghreb).

Bayezid sent a fleet again in 1492, when the armies of Isabel and Fernando of Spain overthrew Granada and expelled its Muslims and Jews. Ottoman expansion into North Africa then accelerated during the early sixteenth century.

Two events, both in 1517, were critical to this expansion. First, the Ottoman sultan Selim invaded Egypt, which along with Syria had been ruled by the Mamluks, a dynasty of elite Muslim slave-soldiers (as the Arabic term "*mamluk*" suggests). This conquest reflected the Ottoman empire's belated movement into the predominantly Arabic-speaking and Muslim territories of what we now call the Middle East. The conquest also reflected the bid of the Ottoman sultans to fashion themselves as successors to the great empires of the early Islamic era, and notably the Abbasid empire (750–1258), that had once flourished in Baghdad. By expanding into Egypt too, the Ottoman empire was able to assert itself in the Red Sea and the Hejaz (the western coastal strip of Arabia), which contained the two holiest cities of Islam, Mecca and Medina.

The second stage of Ottoman expansion, into northwestern Africa, also began in 1517, when Aruj Reis, a Muslim Turkish-speaking corsair from the Aegean island of Lesbos, offered the city of Algiers to the Ottoman sultan in return for a grant of protection. His brother, known as Khayr al-Din (nicknamed Barbarossa, meaning "red-beard"), succeeded him and extended control to Tripoli so that the Ottoman empire was able to claim what is now Libya as well. Ottoman authorities in Istanbul agreed to regularly send to North Africa contingents of elite Janissary soldiers (whose members had been drawn as boy slaves from the Christian communities of the Balkans and converted to Islam). This Ottoman commitment came at a time when the Spanish empire was coveting the southern Mediterranean coastline and was asserting control over the North African enclaves of Ceuta and Melilla.

In 1574 three years after suffering defeat in a Mediterranean battle against the Holy League (which included Catholic Spain, Venice, and other Italian states), the Ottomans confirmed control over Tunis. By 1587 the Ottoman empire recognized three provinces in the Maghreb, centered on Algiers, Tunis, and Tripoli. The

Ottoman empire never absorbed the westernmost part of the Maghreb, namely Morocco, which instead hosted a series of independent Islamic dynasties.

The most important conduit for Ottoman influence in North Africa, including Egypt, remained its dispatch of military officers from Istanbul. However, direct Ottoman influence remained limited so that local Muslim dynasties, what one may call Ottoman subdynasties, emerged. Typical in this regard was the Karamanli dynasty, which ruled Tripoli from 1711 to 1835.

Ottoman rule over North Africa was highly decentralized and left the provinces considerable autonomy in the running of local affairs. Aside from Egypt (where the Nile River supported a densely settled population that was reliant on agriculture), Ottoman rule was generally limited to coastlines, where cities functioned as hubs connecting trans-Saharan and Mediterranean trade routes. The Ottomans did not control the Saharan interior. West of Egypt, the Muslim urban elites of Ottoman North Africa consisted of three groups: Janissaries sent from Istanbul, Mediterranean corsairs, and *ulama* (religious scholars) who functioned as local Muslim intellectual elite. These groups intermarried, producing hybrid elites like the Kouloughlis of Algiers, Tunis, and Tripoli, whose name, meaning “children of slaves,” reflected their partial descent from Janissary contingents. Ultimately Ottoman rule over North Africa was so decentralized and amenable to local autonomy that it may have amounted to virtual independence for the region. This was especially true after 1801 in Egypt, where an Ottoman officer named Muhammad Ali rose to power.

Muslimization under Idris Alawma

Idris Alawma was the Sayfawa dynasty *mai* (“king”) of the west-central African kingdom of Bornu from roughly 1571 to 1603 and was responsible for consolidating power through military campaigns and strengthening Islamic practices and laws within his domains. Bornu, located in the Lake Chad region, encompassed parts of modern-day northeastern Nigeria, Chad, and Niger and was dominated by the Kanuri ethnic group. The Sayfawa dynasty had ruled over Bornu’s eastern neighbor, Kanem, since the eleventh century; however, the Sayfawas were ejected by the Bulala in the fourteenth century and retreated westward to establish their capital, Birnin Ngazargamu, in Bornu. Islam had gained a foothold in Kanem-Bornu several centuries earlier, yet in Africa, Islam was often accepted by the elites, while they governed non-Muslims or nominal Muslims who retained many elements of traditional beliefs and practices. This was the case in Bornu, which had an amalgamation of Islamic and traditional practices prior to Mai Idris’s rule.

The genesis of Idris Alawma’s Muslimization philosophy was his performance of the hajj (pilgrimage) to the Muslim holy city of Mecca around 1571. Just like several other significant rulers of African empires, the *mai* was changed politically, spiritually, and culturally by his experience in the east. He not only renewed his faith but was also introduced to the broader world, specifically to Ottoman political structures and their superior weaponry and military tactics. He recruited several hundred Turkish musketeers and brought them back to Bornu to train his military, assist in securing Bornu’s tenuous borders, and quell all threats to Kanuri economic and political domination. Accounts from the first 12 years of these campaigns has been preserved in the writings of Idris Alawma’s chief imam (prayer leader), Ahmad ibn Furtu, who wrote firsthand chronicles of these expeditions.

Many of Idris Alawma’s wars were fought against the So, indigenous non-Muslim peoples of various tribes in Bornu. Through Muslimization and introduction of Kanuri culture to the

So, the mai hoped to consolidate his internal power. Bornu used the superior Turkish firepower to overwhelm their poorly armed adversaries. Idris Alawma preferred negotiation and persuasion in subjugating his foes, but his war tactics were often swift and brutal. Recalcitrant enemies were enslaved and their villages and crops burned until they capitulated. In some cases, whole populations were forced out of their lands and replaced by settler groups allied to Bornu. These practices, along with intermarriage between the Kanuri and the subjugated or enslaved indigenous populations, further extended and strengthened Kanuri supremacy in greater Bornu. For over a decade, Idris Alawma led a series of campaigns against the Bulala of Kanem and their allies to pacify border raiders and return the state to the Sayfawa fold. The Bulala eventually agreed to a peace treaty and a vassal arrangement but remained independent of Bornu.

Idris Alawma had savvy diplomatic relations with both the Ottomans of North Africa and the Sadians in Morocco. For instance, in order to fend off a feared invasion by the Ottomans across Bornu's northern border, the mai convinced Al-Mansur, the Moroccan sultan, to supply him with weapons and troops ostensibly to campaign against non-Muslims in Bornu. In return the mai recognized Al-Mansur as the commander of the faithful (leader of the Muslims) as a counterbalance to the Ottoman sultan's claim in Africa. All the while Idris Alawma maintained relatively cordial contacts with the Ottomans.

Despite Idris Alawma's Muslimization policies, the government structure of Bornu remained largely traditional and unchanged, with the exception of his adding a *wazir* (prime minister) to the court. He did, however, strengthen the laws against un-Islamic behavior and more readily enforced them. In addition, the *ulama* (Islamic scholars) began playing a larger role in decision making and dispute resolution, and some mundane aspects of the legal system were placed under *qadis* (Islamic judges). The mai also funded construction of larger mosques made from more permanent mud brick. The Islamic, demographic, political, and military reform policies of Idris Alawma had the effect that

➤ A CURIOUS CUSTOM OF THE MAIS

Many aspects of court life in Bornu predated the introduction of Islam and were drawn from traditional central African customs of divine kingship. One remnant practice generally restricted *mais* from being gazed upon or spoken to directly in public except on rare occasions; instead, he resided in a *fanadir* or remained behind a curtain or veil. The fanadir was a large decorated wooden box with bars in the front, not unlike a cage, with a raised padded platform for him to sit upon as a throne. Similar communication practices employed by Muslim rulers in other parts of Africa have been recorded, including kings who would only speak through intermediaries and others who used the voice of *griots* ("praise singers") to communicate to the public. Despite the mai being behind a barrier, those in his presence still remained at a considerable distance and often with their backs to him. Accounts of the *mais'* appearances before their courts reveal that these were highly ritualized affairs that often included a musical procession and formulaic honorifics between the gathered audience and the ruler. Acts of humility by those at the gatherings such as prostration and applying dirt to the forehead were common.

—Brent D. Singleton

he intended. As his predecessors desired, Kanuri and Muslim domination was firmly established in Bornu, and strong economic centers developed in and around the heart of the kingdom. Idris Alawma's reign guided Bornu into an era of relative peace and prosperity.

—Brent D. Singleton

Hindu Village Life in Early Modern Northern India—Zamindars, Caste, Varna, and Jajmani

Village life in early modern northern India revolved around *zamindars* (landlords), local factions, and a system of patron-client relationships called *jajmani*. Although caste (a system of social organization) was important, its influence was connected to other socioeconomic hierarchies and the prevailing system of land ownership and management.

The caste system essentially divided society into two classes: managers and doers, or those who work with their brains and those who work with their hands. The managerial groups in early modern northern India were the Brahmins (traditionally priests), Rajputs (traditionally warriors), and Banias, or merchants of the Vaisya castes, who handled business matters but often controlled land as well.

The word “caste” (from the Portuguese *casta*) first was applied to India’s social structure by Catholic missionaries in the sixteenth century in order to explain the organization of social class (*varna*) and Hindu law, called *varnashramadharma*. This Hindu customary law was not a mere list of rules but instead was a complicated interaction between ideas believed to be eternal truths, and a worldview that categorized all things depending on their ritual purity and inherent power. Powerful objects (such as blood, leather, and corpses) were seen as dangerous and undesirable. Essentially, everyone whose work meant getting their hands dirty was unclean, or ritually polluted, at least to some

extent. Ancient Hindu law books taught that varnas were necessary and needed to protect and support each other. However, these classes were remembered and enforced by a hereditary caste of Brahmin priests.

The varna system was a theoretical basis of village life, but for most villagers in the early modern period *jati*, or lineage, was more important. European travelers at the time often confused varna with jati although not the missionaries who originally coined the term “caste.” One’s jati was either exogamous or endogamous: people either married out of their birth group or extended family or else sought their spouse within it. Generally speaking, varnas were only theoretical categories of little practical use, and they were divided into hundreds or even thousands of jatis. While varna was unchanging and was defined by occupation and ritual purity, the status of a jati could rise or fall depending on the activities of its members. If members of a lineage group behaved badly, their jati might lose status and even fall from a high-ranking varna into a low-ranking one or out of the caste system altogether, becoming untouchables. Every jati therefore had local and regional councils that imposed sanctions on troublemakers, even expelling them entirely if necessary, but these councils also sometimes deliberately plotted collective social advancement by agreeing to adopt the customs of higher castes. In the early modern period, social mobility hinged on the issues of overall sexual morality, widow remarriage, consumption of spirits, commensality, and the type of work that members of a jati performed.

Indian society, however, was not a horizontally constructed layer cake of varnas and jatis. In all villages, the social order was vertically integrated by patron-client relationships, called *jajmani*, uniting high-caste landowners with an array of low-caste servants. Indeed, the term used for “work” in the sense of a job was *naukri*, which meant “service” but implied that one received patronage and protection as a fringe benefit of labor. In most villages, no single family controlled all of the land and labor. Usually village property was owned by several upper-caste families who might be divided along caste lines or some recent or ancient feud.

➤ ITINERANT TRADERS CONNECT THE VILLAGE AND THE WORLD

According to the Orientalist European point of view, early modern India consisted of self-sufficient village republics shaped by primordial institutions such as caste and religion. Above all, according to the early Orientalists, Indian villages did not interact with the outside world: people lived simply, produced what they needed themselves, eschewed trade, and solved their own problems in their *panchayats*, or village councils. This, of course, was simply not true: there were no isolated villages in early modern India. In fact, all over northern India itinerant traders called *beoparis* ensured that each village, district, and region was interconnected in an all-pervasive web of commerce. The term “beopari” means “load-bearer,” and that more or less describes what beoparis did: they hauled heavy commodities like grain from village producers to local and regional markets. Many beoparis were the younger sons of village *rayats*, or peasant

proprietors. Using an initial capital investment provided by their families or perhaps borrowed from village grain dealers, beoparis bought small loads of grain and sold them for a profit at district and regional markets. Few young men remained beoparis long-term. Hauling grain to market, however, was a short-term way to accumulate sufficient capital to begin buying landholding rights, which usually required the payment of a quit-rent to a *zamindar*. Not all beoparis were of the *rayat* class, however. People of almost any caste could become beoparis, and often the sons of laborers could borrow money from a *jajman*, or high-caste patron, in order to earn a nest egg by speculating in the local grain trade. This sort of work enabled young men to marry and settle down usually by becoming a tenant under their *jajman*, whose loan, of course, was repaid with interest.

—James Hoover Frey

Village political life was not as static as early European Orientalist scholars assumed but instead was dynamic and sometimes even exciting. In order to take over and control a village, landlords formed factions, often arrayed along caste lines, and of course each member of the faction was supported by his clients. If a faction controlled enough clients, it could exert a great deal of influence over the composition of *panchayats*. A *panchayat* represented the five *varnas*: the four groups within the caste system and the fifth *varna*, the *panchalas*, or outcastes. Low-caste villagers usually selected a *jati* representative who would support their landowner or his faction. Nor were these factions merely local. The factions into which landlords divided spread across entire districts and regions so that often one or two castes came to dominate land ownership throughout the area.

In northern India, as in most other parts of the early modern world, land ownership was not absolute. Different individuals and groups claimed different rights with respect to the same piece of land. The word for landowner, *zamindar*, was a Persian term used by Mughal revenue officials that literally meant “landholder.” A

zamindar held only the right to collect the ruler’s share of the land’s produce, a tributary tax that was payable in installments often in cash but sometimes in kind. One of the tasks of the *bania*, or village grain merchant, was the conversion of taxes and rents paid in kind into cash or credit that could be used to pay tribute. *Zamindari* grants were obtained from the Mughal emperor or sometimes from a local *raja*, or petty king, and entailed the upkeep of a staff of retainers who dealt with the villagers, measured fields, and assessed the value of different types of crops grown on parcels of land of differing soil quality. In return for managing the often intricate business of revenue collection, *zamindars* were permitted to keep a portion of the land tax for themselves, both as their profit and to cover the cost of collecting the king’s share. Sometimes a *zamindari* estate could be very small: one village or perhaps a part of one village. Often, however, a *zamindari* consisted of several villages or even an entire district. In Mughal political theory, *zamindari* rights could be revoked at will by the king and were not inheritable, but most *zamindars* over time succeeded in making their rights permanent and hereditary.

Meanwhile, those who paid taxes were referred to as *rayats*, a term sometimes translated as “peasant” although that European term can be misleading in an Indian context. Rayats were small-scale zamindars, or village landlords, members of the local landholding castes, who hired laborers to work the land and sometimes rented small plots to subsistence farmers. Rayats and those who worked for them possessed the ultimate right of occupation. A zamindar, according to customary law, could not eject a rayat who faithfully paid the king’s share, while a rayat could not push anyone off the land if they paid their rent. The pattern of rayat landholding was not uniform, however, and this added yet another dynamic to village life. In some places, each extended family of a rayat jati held its own land, but in others the entire jati shared the land’s produce as members of a *bhaiyacharya*, or brotherhood, managing their holdings and making important decisions collectively.

Zamindars and rayats were not the only people who made demands on the produce of the land. Local custom established the pay rates of village servants, which included the landholders’ assistants, Brahmin priests, craftsmen, and others who provided day-to-day services for villagers, and people employed by the panchayat, such as watchmen (*chowkidars*), deed recorders, grain measurers, and so on. The allowances of such people might be a percentage of the harvest or a customary payment in kind, usually measured in *seers*, a unit of weight roughly equivalent to a kilo, or two pounds. Villages were busy places whenever crops were being threshed, for it was at this time that everyone stepped forward to claim their share at the threshing floor.

Yin Yu Tang—Life in the Qing Village

By the 1790s Salem, Massachusetts, then the sixth-largest city in the United States, had emerged as the leading seaport for the rapidly growing commerce with China and Asia. As trade with Asia accelerated, in 1799 Salem-based sea captains and merchants created the East India Marine Society with a founding charter that called for the development of a “cabinet of natural and artificial curiosities.” Such cross-cultural fascination continued into the twenty-first century. In 2003 the East India Marine Society’s descendent organization, the Peabody Essex Museum, transported to Massachusetts a representative eighteenth-century Chinese merchant’s house.

This house, Yin Yu Tang (Hall of Plentiful Shelter), had been originally built in the small rural village of Hongcun in Xiuning County in the hilly farming region of the Huizhou region of Anhui Province in southeastern China about 250 miles (400 kilometers) southwest of Shanghai. The 4,500-square-foot (418-square-meter) house, which was reassembled in Salem in 2003, is a representative model of the home of a wealthy rural merchant family in China at the start of the Qing dynasty (1644–1911). Eight generations of the merchant Huang family lived in the house from its construction in the early eighteenth century until the last family members left in 1982. The house stood empty until it was sold to the Peabody Essex Museum in 1996.

The Huang family constructed Yin Yu Tang following the basic principles of feng shui. The house is two floors high with a small courtyard in the center. Despite its relatively small size, the house could hold many members of the extended Huang family. Sixteen small bedrooms, two at each corner on each level, are connected by a narrow corridor overlooking the courtyard. There are very intricately carved wooden screens that provided the occupants of each room both privacy and ventilation.

The house is built with a timber-frame construction with a tile roof and exterior masonry walls of brick and sandstone. The inner courtyard, which the Chinese traditionally called a skywell, is the main source of light for the house because there were very few windows on the

outside walls. There are two small pools in the courtyard fed by an underground spring. The pools served as a source of water in case of fire and as a place to keep decorative fish.

Family life at Yin Yu Tang was very typical for Qing-era China. In traditional China it was considered normal for all men in a family to marry and bring their wives to live on the family estate and for all women born to a family to marry and go out to live with their husbands. The extended family, three and at times four generations, would live under the same roof at any one time. Life at Yin Yu Tang followed these social patterns very closely.

Residents of Hongcun Village referred to the house as Qi Fang, or “Seventh Branch,” probably indicating that the house was constructed by the seventh son of an earlier patriarch who thereby started his own new family line or branch. Family records indicate that routine Chinese societal patterns occurred here as well. Daughters left the house when they were married, and the newly wedded brides of Huang family sons moved into 1 of the 16 bedrooms of the house. As it was customary for Huang family men, most of whom were merchants, to be away sometimes for one or more years on business, they only came home for occasional visits. The permanent residents of the house were therefore their wives, children, and elderly relatives.

Since the Huizhou region is mountainous, it is not conducive to the growing of rice, southern China’s staple crop. To prosper, males in the Huang family as well as large numbers of the area’s men became merchants who would sell local products and resources elsewhere in exchange for rice and other goods. Other merchants would set up shops in larger urban areas and send their profits back home to their families. They would only make occasional visits to their village to marry, to continue the family line, and to pay respect to their elders.

The Huang family prospered during the eighteenth and nineteenth centuries but experienced decline in the late 1800s. The family sank into debt and around 1900 turned over several rooms in their home to creditors. After the creation of the People’s Republic of China in 1949, the communist government confiscated two rooms for use by peasant families. During the

Cultural Revolution of the late 1960s the building was attacked by the Red Guard, and many of its traditional artifacts were destroyed.

The Double Structure of Japanese Life

Social boundaries in mid-fifteenth-century Japan were not rigid. A peasant might work occasionally as an artisan, merchant, or a part-time mercenary. This relative social mobility continued into the Warring States period (ca. 1450–1600), a time when even a peasant could become a victorious warlord, as was the case with Toyotomi Hideyoshi. Gradually, however, warlords, called “daimyo,” changed the organization of land and people in their domains to meet the demands

Screen depicting Nijo Castle and town, headquarters of the Tokugawa family in Kyoto, Japan, early seventeenth century. (Werner Forman/Corbis)

➤ DANZAEMON

Many individuals took advantage of the evolving status system that separated the samurai from commoners during the early formation of the Tokugawa regime in the sixteenth century. For example, Danzaemon was the hereditary name for a family of leather workers who asserted themselves as the leader of *eta* (outcasts who performed duties seen as polluting, including leather works and funeral arrangements) in Edo (now Tokyo) and the surrounding Kanto area. In 1725, the sixth-generation heir, Danzaemon Shuson (1709–1748), strengthened his family's claim by creating a fraudulent lineage that connected his family to luminaries of the past. Nevertheless, the Tokugawa shogunate recognized this Danzaemon and his family's authority, granting its head power and privileges typically reserved for daimyo, such as wearing certain types of clothing or traveling in a sedan chair, and awarded him a large estate and stipend. The shogunate even allowed Danzaemon to judge and punish *eta* and other outcasts in the area as well as demand tribute from them, making him a semi-independent ruling authority. In return, Danzaemon and his heirs supplied guards and executioners, ensuring smooth operation of the Edo penal system, and leather goods (an industry monopolized by the so-called polluted *eta*).

—Michael Wert

of an increasingly violent country. Daimyo gathered samurai in castle towns, attracting merchants and artisans in the process. This separation of people between urban and rural areas developed under Hideyoshi and became a defining feature of the Tokugawa period (1600–1868).

In the fifteenth century, much of Japan's population worked land under the estate (*shoen*) system. Major Buddhist temples, noble and powerful warrior families, and the leader of the warrior government, the shogun, controlled these estates. As long as the cultivators' estates ensured consistent payment of their tax to the absentee landlord (as many lived in the capital city of Kyoto), local people lived with a relative degree of autonomy. Although estates were divided into subunits, only some of these subunits could be described as villages. Villages possessed no legal definitions, such as a document from a lord

defining them. People living in villages might be called peasants or sometimes merchants, depending on their activity at the time. In general, Japan of this period experienced little division of people based on social status.

The entire geographical and social landscape of Japan changed following the Onin War (1466–1467). Years of succession disputes among several influential families, including the reigning shogun's Ashikaga family, destroyed Kyoto, Japan's largest city. Vassal families across Japan sent armies to Kyoto, leaving a power vacuum in the countryside. Daimyo branch families and individual warriors took the opportunity to assert themselves over their lords, a phenomenon known as *gekokujo* ("the bottom overturning the top"). For roughly a century after the Onin War, daimyo changed the organization of people and land in order to defend their domains. Local daimyo castle towns became the new centers of power.

Hideyoshi was the second of three warlords who succeeded in unifying the country and in doing so finalized the organization of land and people begun by many daimyo in the Warring States period. He removed warriors from the countryside, forcing them to live in castle towns. He disarmed commoners in the countryside by conducting sword hunts to confiscate weapons. Finally, he standardized the measurement of land into easily administrated units through cadastral (land ownership) surveys. The final unifier of Japan, Tokugawa Ieyasu, continued the policy of separating the warriors from the peasants.

During the Tokugawa period (1603–1867), the Tokugawa regime emphasized an idealized society composed of rigidly defined status groups. Under the typical Neo-Confucian (a blending of Confucianism and Buddhism) understanding of a hierarchical yet harmonious society, people were born into their status. The four status groups in order of importance to society were samurai, peasant, artisan, and merchant. In the relative peace of the Tokugawa era, samurai became government officials who possessed the requisite ethical and moral talents to rule. They comprised about 8 percent of Japan's total population and lived almost exclusively in castle towns. Peasants were the second most important group because they produced food, while artisans provided goods and services. Merchants were considered

the lowest class because they only desired profit for themselves. There were also marginal groups such as the *eta*, outcasts who monopolized jobs associated with death, including butchers, tanners, and even drum makers.

In reality, however, status distinctions were not so rigid. Instead, it is important to draw distinctions between occupation and livelihood in Tokugawa society. Occupation refers to the economic activity that fulfills one's obligation to governmental authority. For example, a peasant's duty is to pay his share of the village tax owed to the shogunate or daimyo. An *eta* might be required to remove dead animals or function as an executioner. Livelihood, how an individual makes a living, can include activities not necessarily associated with status. This accounts for *eta* who farmed or peasants who traded like merchants or engaged in by-employments such as raising silk worms. Although the status distinction between samurai and commoner was strict, the system was flexible enough to allow commoners to pursue a variety of activities.

From the late nineteenth century, the status system began to break down. Samurai gradually experienced financial difficulties, often going into debt with the despised merchants. Some samurai abandoned their hereditary occupation, in some cases selling their title to wealthy commoners. Domestic political pressures and foreign intrusion from Western countries hastened the collapse of the Tokugawa regime in 1867. Less than a decade later, the modern, centralized Meiji government abolished the samurai class, thereby destroying the last vestiges of the status system.

Village and Town Life in Europe

Everyday life among the common people of early modern Europe's villages and hamlets was marked by the nature of the relationships between these rural towns and developing—or declining—urban centers and regional capitals. Their continued ability to supply most of the agricultural needs of Europe's cities contributed to their enduring agricultural character and traditional culture. However, most villages also relied on local merchants, artisans, laborers, and small tradesmen to provide services for the residents, thus adding a commercial element to their economies. The rhythms of rural everyday life were punctuated by market days, fairs, religious festivals, and other cultural events sponsored by the church, local elites, guilds, or burgher organizations. In addition, local elites provided the town with political leadership and in some instances prestige. The threat of famine and outbreaks of disease posed an immediate threat to town life, exposed to the uncertainty of such phenomena. Witch-hunts, widespread during early modern Europe, were typically ways of coping with such matters by placing blame on supernatural causes and those unfortunate enough to be accused of practicing witchcraft.

► THE EFFECTS OF ENCLOSURE ON ENGLISH VILLAGES

Land distribution practices during the Middle Ages in Europe parceled land in strips to serfs and peasants adjacent to those of the lord demesne. This communal open-field system led to overgrazing of crops by livestock, which were also shared in common. In contrast, the closed-field system was characterized by small fields surrounded by ditches, earthen walls, and hedges, cutting them off from communal lands for personal consumption and profit. The process known as enclosure, whereby communal lands were fenced in and parceled as private property to small owners, became widespread in England in the eighteenth and early nineteenth centuries. Enclosure limited land usage to the whim of one owner, depriving villages of communal rights to usage of such land. In some instances enclosure occurred due to a decline in population, which reduced the demand on the land and lessened the number of farmers in one region, resulting in the consolidation of holdings under one owner.

The growth of the woolen trades spurred a greater need for enclosure due to the large grazing area needed to feed flocks of sheep. This motivated landowners seeking to become more profit-

able to consolidate their landholdings through enclosure. Increased demand along with a scarcity of tillable land caused rents to rise dramatically in the 1520s to the midcentury. The English Civil War ignited a major surge of enclosures due to the parliamentary support of the rights of landlords and the loss of power of the king, who had been the main advocate against the enclosure process. Widespread enclosures throughout the English countryside resulted in the creation of a hierarchical rural social structure consisting of massive landed estates owned by the aristocracy and the gentry, smaller tenant farmers, and large amounts of laborers who did not own property. Local communities had to reshape their local economies to suit this new arrangement or go under. Towns that were solely dependant on agriculture lost many of their residents to larger urban areas that offered better economic opportunities, fueling the labor needs of the burgeoning Industrial Revolution beginning in England in the late eighteenth and early nineteenth centuries. Towns that already had established links to commercial and industrial enterprises survived the perils of the enclosure movement successfully.

—*Abraham O. Mendoza*

The growing economic vitality of commercial centers throughout England, France, Spain, and the German states of the Holy Roman Empire between the fifteenth and seventeenth centuries allowed adjacent towns and villages to partake in the economic opportunities they generated, albeit to a somewhat lesser degree. Proximity to the great ports, manufacturing centers, and administrative cities such as London, Paris, and the Hanseatic League provided a market and profits for the surplus produce of small agrarian towns and villages. However, the uncertain nature of the international economy could enrich as well as ruin small peasant farmers or even prosperous landed gentry. In towns and villages, dwellers would rely on local artisans, merchants, and craftsmen for finished goods. Small towns did not have the restrictions on manufacturing that guilds had in larger cities, so there was a greater degree of autonomy for small artisans. Doctors,

lawyers, and similar professionals practiced their craft at the local level as well, dependent on the well-to-do town denizens, but were also readily available to socially mobile peasants who lived in the town. The eventual development of the Commercial Revolution in this period would either enrich or impoverish towns and villages, contingent on regional, national, and international economic prosperity.

The cultural and social life of towns and villages differed according to their religious affiliations and their social structure. Following the Protestant Reformation, many towns in northern Europe remained considerably unaffected by changes in the religious denomination of their regional political centers, in contrast to more urban areas. If they changed religions, it was often not due to conviction but rather because of political persuasion coming from the regional capital. However, small towns and villages, both

Protestant and Catholic, continued to have religious festivals and market fairs resulting in communal celebrations involving games, drinking, and music. Local elites and well-to-do merchants helped sponsor such events to add to their luster and prestige among the populace. These elites had a huge impact on local cultural life, given that they represented urban tastes and sophistication to the provincials. Local organizations formed by burghers also subsidized cultural life in towns and villages by providing lending libraries, guild halls, and schools for enlightenment. Local political leadership stemmed from successful town burghers and elites, having already built their reputations on contributions to the town community. Many of these towns were able to purchase charters and rights from the national monarch, excusing them from taxation or granting them privileges such as a royal garrison or stockade in the town.

Famine, pestilence, and witch-hunts also characterized town life in early modern Europe, both in Protestant and Catholic areas. A bad harvest could readily lead to the death of many town residents, which still occurred periodically throughout Europe. Proximity to agriculture did not spare townsfolk from the privations caused by famine. The outbreak of disease, particularly the plague, decimated town dwellers who lived in close proximity to each other, sparing no one regardless of social standing. Typically, famine and outbreaks of disease were blamed on local witches, giving townspeople a ready scapegoat for their frustrations. The witch-hunts of early modern Europe were widespread in small towns, suffering from the hardships of economic peril, bad harvests, and outbreaks of disease.

Village and Town Life in Spanish America

The establishment of Spanish colonial power in Latin America during the second half of the sixteenth century heavily rested on and adjusted to preexisting patterns of urban, economic, and social life. While regions such as central and southern Mexico and the central and northern Andes were densely populated and had consequently developed an ancient urban tradition, the tropical areas of Colombia as well as the grasslands of modern-day Argentina, Chile, and Paraguay were mostly inhabited by nomadic people, with only sparse and temporary settlements.

In colonial Spanish America, the majority of the Spanish and Creole (Mexican-born Spanish) populations lived in cities founded after the invasion. The indigenous population, which still accounted for the vast majority of inhabitants in Spanish America through the eighteenth century, on the other hand, lived in both rural settlements and urban areas. A fundamental aspect of Spanish administration of indigenous territories was the congregation of dispersed indigenous settlements in nucleated centers, with the purpose of better controlling the local population and facilitating the conversion efforts and the economic exploitation of the labor force. These strategies of forced relocation are known with different names throughout the continent: *congregaciones* in New Spain and *reducciones* in Peru. While the rapid depopulation in indigenous territories was one factor that triggered the congregation of different hamlets into a single larger town, there was also a strong ideological component to this decision. As part of the larger colonizing project, the segregation of the indigenous population from Spanish, mestizos, Africans, and other people of nonindigenous descent was an attempt on the part of the Crown to convert and “civilize” the local population in a setting that was free from the corruption and temptation of Spanish city life. In other words, indigenous people were expected on the one hand to embrace European religion and customs while at the same time remaining different from the Spanish ruling class. Albeit uneven, this process of reduction gave rise to an important economic and administrative pattern in Indian villages. A larger town

SPANISH TOWN PLANNING AND BUILDING

Cities, towns, and even small villages in Spanish America have a distinct architectural and urban imprint. City life revolves around the main plaza, or square, delimited at the four sides by important civic or religious buildings. The city hall and the main church are typically found at one of the square's sides. Porticoes ensure a lively street life, where vendors are free to offer their merchandise to passing visitors. The plaza is the generating element for the surrounding city and its wards, organized according to a regular grid. Distributed among even blocks are the residences of different social classes, and usually the higher the status, the closer is the residence to the main plaza. This design is strikingly different from that of contemporaneous Spanish cities, which were designed according to defensive principles and organic growth. While the grid design became widespread thanks to a series of laws dated to 1571, which attested to the necessity of a clear urban design in connection with the tasks of colonial administration, its origin can be found in Amerindian urban design, which in large as well as small centers was based on the centrality of the plaza, the place where sociopolitical, economic, and religious activities took place.

—Alessia Frassani

was given the status of *cabecera* (“head town”), while smaller surrounding hamlets were designated as *sujetos* (“subject towns”). This hierarchical structure was most likely not in place in the pre-Hispanic period. Other institutions also corresponded to this hierarchical structure, such as the *doctrina*, a principal parish church with a priest in residence in charge of the administration of the sacraments in the main church and the other smaller settlements.

Indigenous villages were subject to paying taxes to the Crown. In the early colonial period the collection of tribute was most often carried out by an *encomendero*, a Spanish conquistador who had been granted privileges to extract tribute and labor because of his participation in the enterprise of the conquest. This institution, however, lasted only a generation, being eventually abolished by the Crown, which took direct control of the tribute payment.

Each town was granted autonomous administration, principally through a political institution known as the *República de Indios* (Republic of Indians), which was opposed to the *República de Españoles* (Republic of Spaniards) found in the large cities. The Republic of Indians was governed by a complex hierarchical structure, based on a rotational system of charges. Only males were allowed to serve in the *cabildo* (“town council”), in different capacities and according to their desire of gaining prestige and privileges in their own community.

Finally, another crucial aspect of rural life in Spanish America was the mission. The evangelical project of the Church was carried out by different orders. While the Franciscans were the first to begin the efforts in central Mexico, Dominicans established the largest number of missions in the southern part of Central America and in South America. Finally, the Jesuits took over more remote areas in northern New Spain and the South American pampas (grassland plains). Ideologically conceived in a similar manner to the Republic of Indians, these missionary establishments enjoyed a great degree of autonomy from the larger colonial system. The purpose was to convert the indigenous population to Christianity in a location removed from the corruption of Spanish society. Missionaries were pioneers in Latin America in the study of indigenous languages, which they first transcribed in Latin alphabet, compiling dictionaries and grammars of many local languages. They also involved hosting communities in the sponsorship of religious celebrations and devotional artworks, allowing for the creation of often unique forms of religious behavior and belief.

Despite the efforts on the part of both the Crown and the Church to maintain racial and cultural segregation, the mercantile economy of the Iberian empires, based on maritime port trades and land commercial routes, together with the high demand in urban centers for servant labor, made racial segregation in colonial Spanish America more an ideological abstraction than reality. Large cities, whether based on a pre-Hispanic foundation, such as Mexico City, or established anew by the Spaniards, such as Lima, possessed a substantial indigenous population and were tied to surrounding smaller

towns by a web of social, cultural, and economic ties.

Village and Town Life in Colonial Brazil

As the Portuguese established colonies throughout Asia, the cities and towns were built on the Portuguese model and resembled the Portuguese cities and towns. However, when the Portuguese began colonizing Brazil, their cities and towns developed differently. Brazil was different from Spanish America in that there were no large indigenous empires to conquer. The number of indigenous people living there was small, and they were tribal and lived mostly in the interior. The only obvious import at first was the brazilwood tree, but eventually sugar plantations began cropping up. Brazil was an export-oriented colony from the beginning, and its settlements developed accordingly. Because of the high rate of ships that were going to Brazil in order to pick up the brazilwood and sugar, all of the cities were established on the coast, and all contained ports for trade. In addition, the plantations cropped fairly close to the coast as well; all were no more than a three- or four-day ride from any city. Although most settlements were fairly close to each other, their reliance on Portugal for their governmental and economic institutions meant that no network developed between the cities or the plantations until the mid-eighteenth century.

The cities of Brazil remained few and small throughout the colonial period. Most were established between 1580 and 1650, and by 1650 there were less than 40 cities and towns in the colony. In addition, the populations remained very small; Salvador, its largest city, only had 14,000 residents in 1585. Despite the importance of Brazil in producing sugar and eventually with the discovery of gold, Salvador only had grown to 25,000 residents by 1724. As mentioned above, all of the cities contained ports for trade; however, the residents usually preferred to separate themselves from that aspect. The residential neighborhoods were far from the wharves, especially for the benefit of their wealthier citizens, who did not want to be reminded of the activity while at home. However, the wealthiest colonists did not have a large presence in the cities throughout the year, as the plantation owners favored staying on their plantations, which provided many of the benefits of the cities. Despite the difference in size and composition, the cities did resemble the cities of Portugal in other ways. During the sixteenth century, a large amount of cut stone and tile was shipped to Brazil from Portugal in order to build many of the religious and civic buildings that were aspects of every Portuguese city. Most importantly churches were built, and these buildings became important centers of both religious and civic ceremonies while providing character for the neighborhoods in which they resided.

With the exponential growth of sugar exports in the seventeenth and eighteenth centuries, the plantations, or *engenho*, became important and large settlements. In fact, the existence of plantations meant that there was no need for villages, as the very makeup of the plantations resembled villages. Each plantation contained a manor house occupied by the owner, buildings to house the numerous slaves and employees, buildings for processing the sugar, a chapel, and sometimes even a resident priest. Because of the large number of residents at these plantations, many artisans also came to live there, drawing them away from the cities, which was where they traditionally lived and worked in Europe. The manor house was typically large, two stories, and furnished with many luxury goods imported from Europe. The slaves

were usually housed in barracks-style single-sex buildings, which prevented men and women from developing a family life, even when they shared children.

The final settlement developed to establish the colony was the *aldeia* system. The aldeias were missions established by the Jesuits for the purpose of converting the indigenous population to Christianity. The aldeias also served to resettle the peaceful natives from their own villages. Besides the obvious religious goals, the aldeias also served to help settle the interior, which was lacking in European colonies, and protect it from encroachers. The aldeias were originally meant to produce agricultural products to sell, but the realities were far different. Even though each aldeia had at least 2 resident Jesuits, there were many Jesuits who traveled among the aldeias, which usually spread disease. This was compounded by the fact that celebrations and processions were occasionally held at the aldeias and nearby settlers were invited, and some aldeias had as many as 5,000 residents. Disease killed many of the natives, and some managed to escape, which meant that the aldeias barely produced enough food to support themselves, and sometimes they did not. The Jesuits also managed to become entangled in disputes with nearby settlers, who were eager to use the indigenous people as slaves. In the end, the aldeias were only able to maintain their populations by bringing in more and more indigenous people. Unfortunately this only exacerbated the problem, as the new residents were particularly vulnerable to disease especially because of the forced resettlements and the new sedentary lifestyle.

The settlement of Brazil brought about a different style of colonization unseen anywhere else. For most of the colonial period, Brazil's social life coincided very closely with its economic life. Populations of cities grew and fell around the growth of the export products of different regions. Therefore, the cities remained small and relatively unimportant. The population of Brazil remained divided among the various plantations, whose importance drew people away from the cities. As for the indigenous population, their forced resettlement into the aldeias caused large amounts of deaths due to disease while enabling the Portuguese to settle the outer frontiers where

the natives had previously resided. The aldeia is another example of the economy becoming intertwined with society, as the aldeias were supposed to provide Brazil with a labor reserve. The failure of this system to do that brought the introduction of African slaves to the plantations and mines. This economic order dictated the social and political order, placing the wealthy plantation owners on the top and in the position to influence Brazil's path down to the twentieth century.

Carib Slavery—Spanish Colonial Control over Caribbean Labor

Slave regimes made an early appearance in the Americas, starting with the Spanish who specifically targeted Caribs, especially after having decimated the Taino population on Hispaniola. Spanish colonizers employed slavery as one means of securing labor on the island of Trinidad, in eastern Venezuela, and from the Orinoco River delta to the south of Trinidad. Whether target populations were to be enslaved or not depended on whether the Spanish needed peaceful populations to mine gold and provide needed foodstuffs (through trade or tribute) or instead needed laborers to be shipped to other parts of the Caribbean as slaves.

Spaniards began to trade indigenous Trinidadian slaves to islands in 1503, sending them to the northern Venezuelan coast, where they were used in the pearl fisheries, and soon to Puerto Rico and Santo Domingo. Although Diego Columbus, Christopher Columbus's eldest son and viceroy of the Indies, began exporting Carib slaves from Trinidad to Margarita in 1509, by the following year a royal decree put a momentary

► WHEN DID THEY BECOME CARIB? THE POLITICAL ECONOMY OF A LABEL

The Caribbean Sea was named with reference to the Caribs. Spanish designation of certain groups as *Carib* was motivated by the desire to secure slave labor in ways consistent with the wishes of the Spanish Crown and with the drive for capital accumulation. *Carib* slaves taken from the north-eastern coast of Venezuela were actually branded with the letter “C” on their thighs. The “C” indicated either their destination—Cubagua or Castille—or their origin as Caribs. For the Spanish invaders, there were no concrete cultural traits that defined an indigenous American as *Carib*; instead, if natives responded to Spanish incursions with violent resistance then this so-called warlike act, by definition, merited application of the *Carib* label. As if to dramatize *Carib* savagery, a myth was developed suggesting that they feasted on human flesh as a matter of routine. Indeed, at one time the words “*Carib*” and “*cannibal*” were cognates, the latter a derivative from Columbus’s transcription of the word “*caniba*,” which later became “*canibal*” or alternately “*caribal*.” No actual incidents of cannibalism have ever been documented in the Caribbean. Indeed, the early tales of cannibalism consisted of beliefs masked as factual assertions. For example, Gonzalo Fernandez de Oviedo, a sixteenth-century colonial chronicler, wrote that “the

island of Trinidad . . . is populated by *Carib* Indians bearing arrows. . . . They are a very bellicose people, naked and idolatrous, and they eat human flesh, and beneath these vices one must believe that they have many others.” The myth was enough, however, to disqualify Caribs from Christian salvation and thus human freedom, the subject at the center of the famous debates between Bartolomé de Las Casas and Juan Ginés de Sepúlveda in 1550–1551. To determine where the Caribs were located was no easy proposition, given that Spanish economic needs and early colonial geopolitics shifted frequently. Trinidad’s natives were deemed *Carib* and then not *Carib* in a rapid succession of several edicts. Matters became so obscure that in 1518 the king appointed a judge, Rodrigo de Figueroa, to produce a definitive classification of indigenous groups throughout the territories known to the Spanish. Labels continued to shift until well into the 1700s, and the debate as to whether Trinidad’s natives were *Carib* continued into the 1940s. Many indigenous communities adopted the label for themselves by the 1600s to signify bravery and to signal their resistance to the Spanish. Self-designated *Carib* communities continue to exist today in Dominica, St. Vincent, and Trinidad.

—Maximilian C. Forte

stop to the trade in *Carib* slaves from Trinidad. The main justification was that the island was said to house gold deposits, requiring a peaceful population in place to mine it. Just over a year later, with no gold discovered and Trinidad’s natives engaged in resistance, the king issued a decree that once again legalized their enslavement. Yet another royal edict in 1512 reversed this decision, which was itself reversed in 1518, and reversed again in 1530. Given the assumed proximity of the mythical El Dorado in the land of Meta, presumed to be located in the Orinoco region, Trinidad’s strategic value for the Spanish was heightened in the 1530s. As a consequence, Spanish authorities deemed peaceful occupation of the island to be desirable, leading them to seek out indigenous peoples as partners rather than slaves.

One avenue for Spanish capital accumulation came through the appropriation of native

trade networks. It became convenient to mark as “*Carib*” those native polities that controlled the trade in tobacco and corn and resisted Spanish efforts to encroach upon local exchange networks. As a result, in 1547 the king of Spain officially permitted colonists in Puerto Rico to wage war on the Caribs and to enslave them, specifically targeting native populations in Guadeloupe, Dominica, Martinique, and Trinidad.

By 1642, King Philip II of Spain announced the cessation of military attacks on indigenous communities. Coerced labor was terminated in the Orinoco region in 1686 by Trinidad’s governor as a means of achieving more peaceful relations with aboriginal communities. In that same year, the Capuchin order was instructed by the king to establish missions there. By 1716, *encomiendas*, the Spanish estate system that operated with coerced labor, was abolished throughout the Spanish empire and replaced by

Catholic missions that appropriated indigenous labor for themselves. By 1756, the legal provision for the enslavement of rebel Caribs was finally terminated.

The Catholic Church itself became an economic power in the colony of Trinidad with the establishment of missions from the mid-1600s. The church appropriated almost all the native labor force and became a leading producer of cocoa, perhaps the most lucrative cash crop to be produced in the Caribbean at the time, destined for export to Europe. All natives in the missions were subject to the missionaries for a period of 20 years. At the end of this period of indenture and in keeping with their new status as freemen, a tax was imposed on each of them.

Town Meeting and General Court—New England's Representative Institutions

The General Court, which exercised legislative, administrative, and judicial powers, was the central governing body of Massachusetts Bay colony and the pattern for colonial government in such neighboring settlements as Connecticut, Rhode Island, and Plymouth. The town meeting, an assembly of all enfranchised townsmen, was the primary decision-making body of a town, which was the principal unit of local government in colonial New England.

In March 1629 Charles I issued a charter for creation of the Massachusetts Bay Company, a joint-stock trading enterprise formed by a largely Puritan group of investors to develop trade and settlement in the Massachusetts Bay region.

The charter empowered the company to hold quarterly "Great and General Courts" at which company shareholders or freemen conducted company business and framed such rules and regulations as seemed advisable, so long as they accorded with English law. Although most of the company's Puritan leadership opposed the religious policies of the king, only a minority were so dissatisfied as to contemplate moving themselves and their families to New England. However, in August 1629 a group of future immigrants led by John Winthrop convinced the company's General Court to authorize transfer of the company and its charter to New England, an unprecedented action that in effect transformed the company into a colony and its governing body, the General Court, into a colonial government. The government of Massachusetts Bay colony would thus not be in London but instead would be in America, where in the seventeenth century it was well beyond the effective control of king and bishops. In 1630 Winthrop, who had been chosen as governor, led an expedition of almost 1,000 families, mainly Puritans, to settle along Massachusetts Bay.

Because only Winthrop and a few other members of the 1630 expedition were company freemen and because only freemen could vote in the General Court and only the General Court could elect the governor and his 18 assistants, unrest over the narrow scope of political power in the colony grew quickly, and many settlers petitioned to be freemen. In 1631 the General Court admitted another 118 settlers to freeman status, and in 1632 all male heads of households who were church members of good standing were declared freemen. Because these decisions greatly expanded the size of the General Court, an act of 1634 provided for the election of two or three freemen from every town to represent the local communities in General Court meetings. In 1644 the General Court assumed a bicameral organization, with the governor and his assistants becoming the House of Assistants (today the Massachusetts State Senate) and the town representatives becoming the House of Deputies (today the Massachusetts State House of Representatives). All legislative proposals thereafter required majority support in both houses to become law.

The General Court was the supreme legislative and judicial authority of the colony, able to enact laws and levy taxes. It regulated the economy by setting wages and prices, promoted religion by requiring church attendance, and supported the social hierarchy by enacting sumptuary laws. Especially under Winthrop's governorship, when political power was restricted to church members, the government of the colony was conducted under Puritan principles. However, the government was not a theocracy, for ministers, while extremely influential, were forbidden from holding government office. Magistrates sought and followed the advice of clergymen but were independent from them.

Religion did, however, strongly influence many actions of government, particularly in regard to education. The need to train ministers led to the foundation of Harvard College in 1636, and the need to train children to read the Bible led to a 1647 General Court enactment requiring all towns with 50 or more families to fund a local public school. Puritan dominance also led to strict suppression of religious dissent. In 1635 Salem minister Roger Williams was brought before the General Court and ultimately banished from the colony for preaching separation of church and state. In 1637 the General Court also banished Anne Hutchinson for claiming direct revelation from God and banished John Wheelwright for challenging the religious authority of the government.

Within each of the towns that quickly sprang up in the colony, local government was conducted by town meeting, an assembly of all town freemen. Town meetings elected local magistrates, founded and funded local schools, provided relief to the poor, organized defenses against Indians, built roads and other improvements, and provided all necessary local services. In 1636 the General Court officially confirmed the self-government of colony towns. Over the course of the century, as towns grew in size and population, the powers of the full town meeting passed increasingly to a body of elected selectmen who oversaw the daily functioning of local government. Thus, over time both colonial and town government became less direct and more

➤ CAMBRIDGE AGREEMENT, 1629

At a meeting of the mainly Puritan shareholders of the Massachusetts Bay Company held in Cambridge, England, on August 26, 1629, a group of 12 shareholders led by John Winthrop signed an agreement pledging to immigrate with their families to New England. Because the company charter did not stipulate where company meetings were to be held, Winthrop's group demanded that they be allowed to carry the company charter with them to Massachusetts, thus in effect transforming a trading enterprise into a self-governing colony and the company management into a colonial government.

Although no other colony was without a governing board in London, the General Court of the Massachusetts Bay Company voted on August 29 to allow the transfer of the charter to America. All shareholders who were unwilling to resettle in Massachusetts agreed to sell their shares in the company to Winthrop's group, who then formed the General Court, or governing body, of the new colony when Winthrop's first colonists landed in America in June 1630. By this Cambridge Agreement, the Puritan settlers of Massachusetts, thousands of whom entered the colony during the Great Migration of the 1630s, ensured their ability to govern themselves, particularly in matters of religion, without direct interference from Crown or Church.

—John A. Wagner

representational, although the influence of direct democracy is still strong in modern New England.

■ Introduction: City Life around the World

During the early modern period, cities all over the world changed, often due to the dispersal of Europeans and the opening of trade networks. Some new cities were built in previously unsettled locations, but the introduction of new trade routes had an impact on cities existing long before the age of European contact.

Colonial cities were unique in some aspects. They performed a dual function in that they were the social centers for the colonists, but also served as financial centers for both the colonist and the metropolitan (that is, the mother country). Colonial cities usually displayed a hybridization of the native and foreign cultures, and they depended on both the natives and the metropolitans for their existence. All of the major institutions provided by the metropolis, from civic to religious, were housed in the cities, and no matter how well agriculture or mining were developed, they would have had no value without the city because that was where the commercial exchanges occurred. Even though colonial cities all over the world had many similarities, they did show regional variations, reflecting the personalities of the indigenous people as well as that of the colonizers. While these cities were built on the models of European cities, they often took on their own characteristics, in an adjustment to the surrounding social and financial cultures.

Even those cities that were not directly colonized by Europeans were still affected by the increase in trade. Of course, the amount of change was relative to the amount of contact experienced in the various regions. For instance, the African cities that existed along the trans-Saharan trade routes flourished with the gold and salt carried north, and many luxuries that came in from Europe and China. After the Portuguese began interacting with the Africans, and the slave trade intensified throughout the sixteenth century, these cities diminished as the Europeans began depending on the sea routes for their trade with Africa and Asia, leaving the land routes insignificant. In India, there were many factors that led to its urbanization in the fifteenth century under the Mughal empire, but one of these was

the increased trade with the Europeans. As the popularity of Indian products grew in Europe, the cities of India also grew increasingly larger and wealthier. In contrast, the cities of East Asia were less affected by European influence, mostly because the foreigners were kept at arm's length. In Japan, first the Portuguese and then the Dutch were isolated to a small islet called Dejima (Nagasaki) by the mid-seventeenth century, limiting the influence they could have over Japanese society in Tokugawa Japan. China's case was a bit different, as they also tended to keep the Europeans at arm's length, but did not isolate themselves to the point that their neighbors did. However, the Chinese government largely ignored the coast and did not invest much into building up its defenses or cities because the scope for trade on the southern coast had been traditionally limited, and therefore it concentrated more on building up northern defenses and monitoring inter-provincial trade. Therefore, the coast in provinces like Guandong (Canton) were mostly left to their own devices, allowing private enterprise to flourish, and the trade with Europeans grew. While the coastal cities did not attain major importance until the nineteenth century when trade reached its full intensity, the beginnings can already be seen in the seventeenth century in cities such as Canton, Xiamen, and Ningbo.

—*Monique Vallance*

For Gold and Slaves—Africa's Coastal Cities

The emergence of African coastal cities (most importantly those of West Africa) has been partly traced to the European expansion of the fifteenth century. The expansion was economically motivated by the desire to get to the source of gold, which the Portuguese believed was in West Africa. The first area of the African coastline to be explored was Cape Bojador, in 1434. Subsequent voyages led to the exploration of Cape Blanco, the mouth of the Senegal River, and the Cape Verde Islands in 1434, 1442, and 1444, respectively. The Portuguese established trade relations with Africans along the coast, and items

➤ BENIN

Benin Kingdom (located in present-day Nigeria) is one of the centralized states of the West African forest region. Unlike some African coastal states such as Bonny that owed their rise and expansion to the European presence along the coast, Benin developed as a result of such factors as social organization, short- and long-distance trade, and the emergence of a dynasty of divine kingship. In the fifteenth century, the Portuguese were the first Europeans to establish contact with Benin Kingdom. Coincidentally, the Portuguese came to Benin at a time when the empire was involved in military expansion that led to the subjugation of its neighbors. Benin, like many African states, was thus able to sell its war captives to the Americas. Many of these slaves worked on Portuguese plantations in the Madeira Island of West Africa. Between the sixteenth and seventeenth centuries, Benin did not sell slaves to the Europeans but instead sold commodities such as pepper, ivory, cotton cloth, and gum. The Europeans then sold these commodities to the Akan of present-day

Ghana in exchange for gold. Benin's king exerted a monopoly on commodities such as firearms, pepper, and ivory. By monopolizing the trade in these items, the king was able to wield considerable power. Benin resumed the sale of human beings to the Atlantic slave trade in the eighteenth century.

Benin's relations with the Europeans were not only in the areas of commerce and trade. The kingdom was one of the first African states to welcome European missionaries. The missionaries were able to preach and convert some Africans to Christianity. In general, these first attempts at Christianizing Africans failed because the missionaries condemned African traditional religion and culture. Unlike most African states, such as Old Oyo empire that fell as a result of internal crises and war, the kingdom of Benin survived until 1892 when the British, during the so-called Scramble for Africa, attacked it and carted away numerous artifacts of enormous value.

—Saheed Aderinto

such as gold, ivory, copper, and human cargo were bought and sold. Fortresses were built as temporary trading and military posts. Elmina Castle, located in present-day Ghana, was the first permanent European trading post in Africa.

The discovery of the New World in the late fifteenth century, the near extermination of the indigenous Native American population, and the beginning of plantation agriculture and mining activities radically changed the pattern of Afro-European relations for more than three centuries. The transatlantic slave trade emerged because of the need for black labor to augment the dwindling indigenous population. Slaves for the transatlantic voyages were derived from a variety of sources, which included but were not limited to raids and wars. Debtors as well as convicts or people accused of crimes such as robbery and witchcraft also formed part of the human cargo sold to the Americas. A large percentage of African slaves sold to the Americas came from the hinterland of the Slave Coast (the heavily populated area that stretched from modern Togo to Cameroon and included the Bights of

Biafra) and the Gold Coast (parts of present-day Ghana and Liberia).

All coastal African states understood the need to protect their trade monopolies with the Europeans and their hinterland neighbors. The people of the hinterlands who were the major suppliers of slaves were not allowed to trade directly with the Europeans. It was also difficult for Europeans to break the monopoly of their coastal trading. Up until the opening decades of the nineteenth century, Africa's tropical environment was a major health threat to Europeans. Sailors recorded increasing mortality rates as trade intensified. Surviving along the coast was a major challenge, and venturing into the hinterland meant courting disease.

Also, the fact that the European was an unpopular figure was another factor that might have persuaded European traders to respect African chiefs and shun the idea of attempting to bypass them by venturing into the hinterland. The coastal city-states continued to monopolize trade until the late nineteenth century, when new economic and political factors combined

with medical and military revolution motivated the scramble for Africa and the demise of the sovereignty of both the coastal and hinterland Africans.

Trade and Culture Flourish in Africa's Desert Cities

The trade routes that crisscrossed the Sahara spawned a large number of great cities. Saharan trade began several thousand years ago, but it was the arrival of the camel in the third century CE and the spread of Islam across the Sahara in the seventh and eighth centuries CE that accelerated the growth of an expansive network that united North Africa with West Africa through the “ocean” of the Sahara. Camels carried an abundance of material wealth, while Tuareg, Berber, and Arab merchants conveyed cultural and intellectual wealth in their encounters with local populations. The result was a series of trade relations and civilizations, heavily defined by Islam, stretching from North Africa through oasis cities to cities of the Sahel in West Africa and back again.

Long-distance trade stimulated urban growth, and powerful cities developed at the crossroads of trade. By the fifteenth century, gold and salt were in the greatest demand, as only certain goods were suitable for long-distance trade. Other raw materials included copper, iron, ivory, kola nuts, and spices such as cloves and pepper. Books and high-value manufactured goods were also traded regularly. The Songhai empire (1464–1591) that controlled a large portion of West Africa imported shoes from Morocco, cloth from Italy, and silk from China. Between the eleventh and fifteenth centuries, artisans in the city of Djenne (in present-day Mali) produced intricately

designed red-painted terra-cotta vases, and the kingdom of Benin (ca. 1170–1897, in present-day Nigeria) was widely known for its ivory carvings and bronze casts, compensating well for its lack of a gold supply. Slaves were also valuable commodities and were traded frequently. The trans-Saharan trade partially depended on slavery to produce many of the goods that it channeled. Although slavery in West Africa was far different than later manifestations associated with the transatlantic slave trade and slavery in the Americas, slaves during this time in West Africa mined minerals, harvested agricultural products, and wove cotton into cloth, serving a dual purpose as both labor and merchandise.

Across these regions of Africa, cities were chiefly organized around the mosque and marketplace. The spread of Islam and the cultures of African Muslims, including Arab and African cultures, went hand in hand with the growth of trade. Islam was the majority religion in North Africa and most of the Sahara by the eighth century and became the religion of most people in the region by the fifteenth century. Many of the world's greatest mosques developed in these cities, such as Al-Azhar in Cairo, Chinguetti Friday Mosque (in present-day Mauritania), and the Great Mosque of Djenné. Likewise, some of the most important centers of Islamic scholarship (*madrasas*, or universities) emerged here too, offering many areas of study, including Islamic law, algebra, poetry, history, theology, and philosophy. Many of the cities famed for their universities, such as Cairo, Fez, and Marrakesh (in present-day Morocco), Timbuktu (in present day Mali), Djenne, and Gao (capital of the Songhai empire, in present-day Mali), were also the largest in the region. By the fourteenth century the population of Marrakesh grew to 300,000, and the population of Cairo grew to 500,000. In the late sixteenth century the population of Gao climbed to 75,000. Other cities, such as Chinguetti and Sijilmasa (in present-day Morocco) were oasis cities much smaller in population but no less intellectually vibrant. Perhaps no city, however, could rival the intellectual vibrancy of Timbuktu and its mighty Sankoré Madrasah, as illustrated in a famous proverb, “Salt comes from the north, gold from the south, but the word of God and the treasures of wisdom come from Timbuktu.”

► TIMBUKTU

Timbuktu was, for centuries, a metaphor in the Western world for the distant and exotic. It was founded in the eleventh century by the nomadic Tuareg traders, and even the story of how it came to be named has its own mythology. The most common legend was that in the course of their travels, the Tuaregs established a permanent settlement near a well, *tin* in their language, and would entrust their possessions to an honest woman named Buktu. The story goes that ultimately, in order to describe the place, the Tuaregs simply combined the two words: Tin'Buktu, or the "Well of Buktu."

Mythology aside, the history of Timbuktu's rise and fall is quite dramatic. At first merely a camp situated strategically between the Niger Valley and the Sahara, it became a major trading post between West Africa and the world north of the Sahara, as western Saharan trade routes were disrupted by the Arab invasion and Berber aggression. Gold, salt, copper, and slaves were the commodities of choice. Timbuktu served as the

commercial and religious capital of the Songhai empire (in present-day Mali), rivaling the political capital of the empire, Gao, in influence. Travelers told stories of its infinite wealth, and its schools and libraries attracted Muslim scholars from around the world. Thousands of texts generated there still exist, and many are housed in libraries and archives like the University of Sankore and the Mamma Haïdara Library. The city enjoyed a prosperous golden age between approximately 1300 and 1600, followed by a slow decline after the demise of the Songhai empire and the redirection of trade to the Atlantic and Mediterranean coasts by the 1600s.

The city became one of UNESCO's World Heritage Sites in 1988. It has been threatened by the continuing desertification of West Africa, but there have been efforts to preserve the city. In 2005 it was removed from UNESCO's list of endangered sites.

—Allison Sellers and Joel E. Tishken

As empires rose and fell, trade networks ebbed and flowed along with the cities central to these networks. The fortune of many cities declined with the advent of Atlantic maritime trade with Europeans starting in the late 1400s. Trans-Saharan trade managed to survive, in a diminished form, and continued even after colonization. Many of the cities that were born at its termini remained important urban and intellectual centers long after the trade's peak, such as Cairo and Fez, while others, such as Chinguetti and Sijilmasa, are largely ruins.

Constantinople under the Ottomans

The prophet Muhammad is quoted as saying that the city of Constantinople would fall by the hands of a Muslim army. It was the Ottoman sultan Mehmet II, later known as Mehmet the Conqueror, who fulfilled this prophecy and seized the city in 1453. The city's name was changed to Istanbul, and the names of many former prominent buildings such as the basilica of the Haghia Sophia, which became a mosque directly after the conquest, were changed as well.

Ottoman Istanbul was a great and thriving city with a diverse and active population. In addition to the main Muslim population of Turks,

➤ SINAN AND BALYAN—OTTOMAN ARCHITECTS

Yusuf Sinan was born around 1490 near Kayseri and died in 1588 in Istanbul. Commonly known as Mimar Sinan or Architect Sinan, he was the most important architect of the Ottoman sultans in the sixteenth century. His works were considered the peak of classical Ottoman architecture, and his reputation as one of the most advanced builders, engineers, and architects of his time earned him comparisons to Euclid and Michelangelo. Sinan combined artistic expression with sound engineering and created several architectural masterpieces, such as the Sulaymaniye Mosque in Istanbul and the Selimiye Mosque in Edirne. His work has been catalogued, and of the 470 buildings attributed to him, 204 are still remaining.

The Balyans were an Armenian family who over five generations provided the Ottoman sultan and the city of Istanbul with some of their finest architects and builders. During the eighteenth and nineteenth centuries they planned and built many public, sacred, and private buildings, such as mosques, churches, schools, palaces, dams, factories, and residential buildings. Their contractors were primarily the royal family and other members of the elite circles. With their buildings they shaped the European image of Istanbul in the latter days of the Ottoman empire. As architects, they preferred Western-style design; however, they included Ottoman-Turkish styles too. Their largest and most renowned building complex is the Dolmabahçe Palace, residence of the sultan since the middle of the nineteenth century.

—Sebastian Maisel

Albanians, and Arabs, there were Greeks, who returned in large numbers after the fall of Constantinople, and Jews, who emigrated from other European countries in order to escape oppression and discrimination. In Istanbul they enjoyed protection and freedom as *dhimmi*, or people of the book, a special provision in Islam regarding other monotheistic beliefs. Starting in the seventeenth century, Armenians from all territories of the Ottoman empire moved to Istanbul.

European merchants came to Istanbul from Italy, Spain, and the Habsburg empire. Nevertheless, the main cause of constant growth and urbanization was an active Ottoman government

policy of relocating people from the countryside. During the conquest of the city only 36,000 people inhabited the area. Within a century, the number rose to over half a million. By the end of the nineteenth century it climaxed when the population of Istanbul reached over 1 million.

All of the different people contributed to the urban development of the city, and soon a distinct Ottoman architecture was recognized in the public and sacred buildings as well as the palaces. As is common in Islam, the purpose of those buildings was multifaceted. They included mosques as places of worship but also several places of learning and scholarship, the medrese, courtrooms, and mausoleums. The imperial status of Istanbul reached its peak during the reign of Sulayman the Magnificent and the tenure of his star architect Sinan. Sinan's life and career were exemplary for the time period. He was recruited and trained under the devshirme system and rose through the ranks of the Janissaries, where he received the best education possible at this time. The sultan made Sinan his chief architect, and it is said that Sinan built over 300 mosques, palaces, hospitals, schools, bridges, magazines, mausoleums, and baths. The Suleymaniya Mosque can be described as his masterpiece. Sinan modeled it to counter the Hagia Sophia, but although smaller in size, the mosque with its symmetrical and rational design, its four minarets, and the splendid courtyard complex surpassed the former role model and created its own unique style. Future sultans continued building mosques and palaces along the Bosphorus.

While sacred buildings were normally built of stone, those for the public, and even the palaces, were often made of wood. Such were the living quarters and markets, where each community and each guild was assigned a special restricted area. As such, public life and economic activities were highly regulated. Two groups of administrators stand out from a city that otherwise did not have a modern sense of citizenship. On one hand were the government officials, such as police force, fire brigades, and security guards, who were mostly concerned with upholding law and order. On the other hand we find religious leaders whose primary function was to apply the law. However, neither of the two was able to prevent occasional fires from

ravaging through the city and destroying much of the wooden structures.

The city was divided into four administrative units: the main city of Istanbul as well as the three suburbs of Galata (the Christian quarter), Eyyub, and Uskudar or Scutari on the Asian side of the Bosphorus. For over 450 years Istanbul was the center and capital of the Ottoman empire. The sultan governed the empire from the Topkapi Palace, a large complex of private and administrative buildings. After Selim II brought relics of the prophet Muhammad back to Istanbul, the city became the religious center of the empire too. The sultan adopted the title of caliph, thus reuniting political and religious authority in one person.

But soon began the decline. Corrupt officials, competing military leaders, the absence of reform, intrigues within the ruling family, and the partitioning from Western economical concepts led to the slow but constant loss of power, territory, finances, and authority. Although the facade of Istanbul remained decorative, people were referring to the sultan, his city, and the empire as the “sick man of the Bosphorus.”

Urbanization in Early Modern India

There has been a long history of urban centers in India, starting with the earliest Indus River societies. This heritage was strengthened by the Muslim arrival in India when they brought with them their own urban experiences and orientations. It has been argued that early Islamic society and culture essentially arose from within an urban

environment and depended on it to consolidate and demonstrate Muslim power. It was inevitable that the mingling of the indigenous and Islamic trends would find expression in the extensive urban centers of early modern India.

In seventeenth-century India almost 15 percent of the population (approximately 16 million to 17 million people) lived in urban settlements that ranged from the country town, known as a *qasbah*, to very large concentrations of the population in sprawling cities. It has been estimated that at different times in the seventeenth century, the three large urban cities of Agra, Delhi, and Lahore (in northern India) all had populations over 500,000, and the cities of Ahmedabad and Surat (in western India) as well as Patna and Dacca (in eastern India) each had populations over 200,000. It is interesting to note that both in the percentage of people living in the urban areas and in the number of cities with populations over 100,000, India was probably more urbanized than Europe in the seventeenth century.

Urbanization demonstrated a particularly rapid growth in the early modern period because of the relative stability provided by Mughal rule, the imperial penchant for grand architectural statements, the development of a communication infrastructure that facilitated economic exchange between town and country, and a buoyant economy made possible by agricultural productivity and the considerable international appetite for Indian products (particularly textiles).

Many scholars have emphasized essentially the symbolic role of cities in India as expressions of imperial power and spiritual authority. The administrative centers established in Delhi, Lahore, and Agra attracted religious leaders and new places of worship, and cities such as Benaras became centers of pilgrimage that fostered artisanal, commercial, and service classes. However, while it is undeniable that many cities originated as garrisons, provincial capitals, or sites of pilgrimage, this tendency of concentrating on military, administrative, and ecclesiastical functions as the primary reasons for the growth of cities in India ignores their economic roles. For example, predominantly mercantile and manufacturing centers became the locus of administrative and political authority in cities such as

► DELHI—FROM ANCIENT SETTLEMENT TO THE EARLY MODERN CAPITAL OF THE MUGHALS

Delhi, the long-standing political capital of India, has its origins in ancient myth and lore. It became a prominent center under the Rajputs in the eleventh century. Since that time successive Muslim dynasties (the Khiljis, Tughluks, and Lodhis) in the fourteenth and fifteenth centuries had sporadically used it as a seat of imperial power and added extensions and encampments to it depending on their needs and interests. But it was under the Mughals, especially under Emperor Shahjahan in the seventeenth century, that it became a relatively unified city and (except for brief periods) the unquestioned center of royal authority.

Starting in 1638, Shahjahan built the inner core of the city (then called Shahjahanabad, now Old Delhi) with its walled semicircular area interspersed by several gates. In this area, the Mu-

ghals built the imposing and lavish architecture expressed in the Red Fort, the Jama Masjid, many tombs and mausoleums (several listed as World Heritage sites), and elaborate and splendid gardens. Mughal rulers also presided over an exquisitely refined courtly culture. Most of them were enthusiastic patrons of the arts and culture, and poetry readings, musical soirees, and sumptuous festivals marked their rule over Delhi and made it a glittering showcase of Mughal glory and enlightenment. Unfortunately, Delhi was sacked by the Persian invader Nadir Shah in 1739 and was badly damaged during the British conquest of the city during the Revolt of 1857. Today, Delhi, comprising both Old and New Delhi (the latter built by the British), remains the capital of India and its third-largest city.

—Ahrar Ahmad

Patna, Ahmedabad, and Dacca. In addition, cities that specialized in a particular manufacturing technique, craft skill, or local commodity, such as the port cities of Surat, Masulipatam, and Hoogly, gradually became economically significant centers as well. Thus, Indian cities served as central places or hinges in the complex network of economic, political, and cultural forces operating at the time.

There was an ambiguous relationship between the imperial state and the city. In many cities, especially provincial capitals, imperial authorities would have officers and functionaries (e.g., chief of police, judges, etc.) who helped to establish some degree of control and authority. However, many of the services such as water, garbage disposal, maintenance of religious centers, and other public works mostly remained under private control and initiative. Moreover, the resources and power of commercial groups allowed them to take independent decisions on most economic matters (as long as they did not specifically defy the emperor) and thus served to jeopardize the growth of administrative autonomy, continuity, or commitment.

—Ahrar Ahmad

Macao and Nagasaki—Containing the Outer Barbarians in East Asia

The Age of Exploration led to an explosion of trade and commerce between Europe and all parts of Asia. While the Europeans were able to colonize parts of southern and Southeast Asia, they were never able to properly colonize eastern Asia. As the Europeans dealt with China

and Japan, they found themselves subject to the whims of the individual governments and were never able to gain the supremacy they had gained in the other parts of Asia due to the restrictions placed upon them. They quickly learned that if they wanted to maintain trade in eastern Asia, they would have to follow without complaint the restrictions placed upon them.

When the Portuguese settled Macao in 1557, it was at the invitation of the Chinese government. The reason the Chinese government allowed the Portuguese to have a settlement in the Cantonese peninsula is not certain, but what is known is that the Chinese retained ownership of Macao, while the Portuguese paid a tribute or rent to the government every year. The Chinese had no interest in mixing with the “outer barbarians” and took steps to ensure that the Portuguese would remain separate from the Chinese population. In 1573 a wall and gate, the Porta do Cerco (Circle Gate), were erected by the Chinese. The Chinese built this gate in order to prevent any of the Portuguese from crossing

into China. Inside the gate there was little agricultural land, meaning that the Portuguese had to be dependent on the Chinese and their regular shipments of food in order to eat. The Portuguese did set up their own colonial government, but this was only for administration purposes, as Macao remained under Chinese sovereignty. Despite their attempts to establish their own colonial government in Macao, the Portuguese were never left to forget that they were at the mercy of the Chinese government at all times. Anytime they angered the Chinese officials the gate was left closed for a few weeks, which halted their food shipments, in order to remind the Portuguese of their dependent status. The Chinese were also apt to interfere in Portuguese affairs as they saw fit, and while it angered the Portuguese, their trade base at Macao was too important to risk angering their hosts.

The settlement in Nagasaki began in a different way. Portuguese sailors “discovered” Japan by accident after being shipwrecked on the shores of Kyushu in 1542 or 1543. By the

➤ A FIRSTHAND DESCRIPTION OF DEJIMA

Engelbert Kaempfer (1651–1716) was a German physician in the employ of the Dutch East India Company. He wrote a three-volume book titled *The History of Japan, Together with a Description of the Kingdom of Siam, 1690–1692*. This book serves as a memoir of his time in Asia with the Dutch and gives historians a descriptive insight into how restrictive the Japanese were toward the Dutch living on Dejima:

“But I proceed to a more particular description of the Dutch prison in Japan, for so I may deservedly call their habitation and factory at Nagasaki. . . . [W]e live all the year round little better than prisoners, confin’d within the compass of a small Island, under the perpetual and narrow inspection of our keepers. ‘Tis true indeed, we are now and then allow’d a small escape . . . forasmuch as it is never granted to us unless it be to pay our respects to some great men, or for some other business, necessary on our side, and advantageous for the natives. Nor doth the coming out even upon those

occasions give us any greater liberty, than we enjoy at home, as will appear by the great expences of our journies and visits, great or small, by the number of guards and inspectors who constantly attend us, as if we were traitors and profess’d enemies of the Empire.”

He also describes the yearly trip to Edo that the Dutch were required to take to pay tribute to the shogun. “Upon the journey it self we are not allow’d any more liberty than even close prisoners could reasonably claim. We are not suffer’d to speak to any body, not even without special leave to the domesticks and servants of the Inns we lodge at.”

—Monique Vallance

Engelbert Kaempfer, *The History of Japan, Together with a Description of the Kingdom of Siam, 1690–1692*, trans. J. G. Scheuchzer (New York: Macmillan, 1906), 2:174, 191, 192.

late 1540s Portuguese ships began arriving into Kyushu in order to trade, and a trading center quickly grew, with Nagasaki at its center. With the merchants also came Jesuit missionaries. Priests such as Francis Xavier set up missions in Nagasaki, and the Christian religion began spreading rapidly. By the 1580s there were more than 200,000 Japanese converts, most of whom were among the poorer peasants, but Christianity also reached the higher strata of society. The Tokugawa dynasty began in 1600, and as the century wore on, the shoguns progressively became more isolationist. This was mainly due to the arrival of both the Spanish and the Dutch, who were attempting to usurp the Portuguese monopoly in Asia. The bickering among the Europeans caused the Japanese to mistrust the Europeans' intentions toward Japan and especially their religion.

The fear of the Europeans' religion was substantiated as more and more people converted to Christianity. The concern did not come from the religion itself but rather from what Christianity represented: the worship of a foreign god and the tool of foreign kings.

A subject who worships a foreign god may not be as obedient, and this was a threat to their power. This combined with several clashes between European and Japanese ships prompted the shogun Tokugawa Iemitsu (1604–1651) to issue several antiforeign edicts. In 1633 he decreed that Japanese subjects could no longer travel abroad. Then, edicts in 1634 and 1635 restricted the number of Portuguese in Japan and their movements. In 1636 he converted a strip of sandbar in Nagasaki into an artificial islet of 29,900 square yards (25,000 square meters) called Dejima and decreed that this was the only area in which the Portuguese could reside and conduct their trade. This situation did not last long, as the Shimbara Rebellion, a local rebellion that was politically motivated, took on religious connotations after flying Christian banners. This convinced Iemitsu that he needed to rid Japan of the Christian problem, and he expelled the Portuguese traders.

By 1640 the Dutch were the only Europeans left in Japan, and Iemitsu ordered that they move from their base in Hirado to Dejima. The Dutch were very closely monitored by the Japanese by

a variety of officials, all of whom were paid by the Dutch East India Company. They could not leave the island except for their annual trip to Osaka to pay tribute to the shogun (again, at their own expense). The Dutch were expected to file a report once a year, and all ships arriving from Holland were inspected for weapons and books containing religious material. They were also forbidden from holding religious services on the island. Despite this the Dutch did have a bit of a cultural influence, as Dejima became known as a scientific learning center because many of the books imported from Europe were sold in Japan. This was known as Raganku (Dutch Studies), and many samurai traveled to Dejima to partake in them. Relations continued in this very limited fashion until 1857, when the Dutch trading post was closed.

Both Macao and Nagasaki had dual purposes: to serve as trading centers with the foreign merchants as well as to control how much influence they were able to exert over the native population. Macao and Nagasaki also worked to keep the colonial ambitions of the Dutch and Portuguese at bay while giving the Chinese and Japanese governments the upper hand concerning trade and policy.

Ayutthaya as a Cosmopolitan Center

Phra Nakhon Si Ayutthaya, or the Kingdom of Ayutthaya (1350–1767), with its eponymous capital, was officially proclaimed by a prince of the U-Thong dynasty who reigned as King Ramathibodi I (1350–1369) over a loose collection of frequently warring self-governing principalities.

➤ AYUTTHAYA'S PALACES

The kingdom of Ayutthaya was renowned for its architecture, especially for the splendor of its many royal palaces and 400 temples (Wats). Its eponymous capital featured three impressive royal structures: the Grand, or Ancient, Palace; Chantharakasem Palace (Front Palace); and Wang Lang (Rear Palace). Ramathibodi I, the founder of the kingdom, oversaw the construction of the Grand Palace with its five royal halls (Aisawan Mahaprasat, Mangkhalaphisek Mahaprasat, Phaichayon Mahaprasat, Phaitun Mahaprasat, and Trimuk Hall), where he and his successors ruled for 98 years. In 1448 the Grand Palace was rededicated as Wat Phra Si Sanphet, becoming Ayutthaya's most revered religious temple and extending the boundaries of the royal compound.

In 1569 Chantharakasem Palace was constructed by Maha Thammaraja (r. 1569–1590) as a residence for his son, the crown prince and future king Naresaun (r. 1590–1605). Wang Lang was originally used as royal gardens and became a royal residence for Naresaun's brother, Ekathotsarot (r. 1605–1610). The palace was built by his father King Maha Thammaracha and became the preferred residence of royal family members during the later years of the kingdom's rule. Much of the splendor of Ayutthaya has been lost, its palaces and temples razed by the Burmese in their conquest of 1767 and left to decay in the jungle.

—Shelley G. Allsop and
Samaya L. S. Chanthaphavong

Ruins of Wat Phra Sri Sanphet at Ayutthaya, the most dominant state in what is now Thailand from the middle of the fourteenth century until the eighteenth century. (Dreamstime)

Known to Westerners as Siam, the kingdom grew by absorbing its neighbors, including the kingdoms of Lopburi and Sukhothai, and extending its boundaries as far as Angkor. In time the kingdom encompassed an area that covered all but the northernmost and easternmost provinces of present-day Thailand as well as parts of the Bilauktang and Dawna mountainous regions of Myanmar. Hosting diplomatic envoys and commercial agents from China, Britain, Portugal, and Spain, Ayutthaya's strategic location made it a center of domestic and international trade and the region's major cosmopolitan center.

Historians believe that Prince U-Thong originally migrated to the rich plains of the Chao Phraya basin from the northern provinces in a bid to escape a cholera epidemic. He chose an agriculturally and economically strategic site at the convergence of three major rivers: the Chao Phraya, Lopburi, and Pa Sak (north of present-day Bangkok). The city of Ayutthaya was located on an island, with the three rivers surrounding it forming a defensive moat. Additional access to the sea supported overseas trading, and the busy port of Mengui (Bay of Bengal) ensured that Ayutthaya became one of the richest economies in Southeast Asia.

The kingdom arose as a commercial and cultural center, particularly during the guidance of Ramathibodi II (r. 1491–1529), by taking advantage of its strategic geographical location. Merchandise flowed in from the Malay Peninsula, India, Japan, and China from Arabian and Persian cities and, with the establishment of Europe's East India companies, Spain, Portugal, France, and the Netherlands.

From the fourteenth to the eighteenth centuries China was a major trading partner of the kingdom. This was frequently a tumultuous relationship, requiring Ayutthaya to pay tribute to the Celestial Empire. Under the Ming, China came to reassess the importance of private trade and awarded the kingdom favored trading status. Chinese merchants who settled within the kingdom established a commercial network, and Ayutthaya came to specialize in trading Chinese luxury goods, especially silk and ceramics, throughout the region. Japanese merchants also established quarters within Ayutthaya, directly opposite the Portuguese settlement, providing a direct trading route between Southeast and East Asia. Ayutthaya welcomed European merchants and diplomats as early as 1511, when Portuguese diplomats arrived by way of Malacca (Malaysia). Ayutthaya and Portugal signed a treaty in 1516 that allowed for Portuguese settlement, trade, and religion in exchange for Western firearms.

Ayutthaya became a pawn for competing European interests, but for a period its rulers succeeded in maintaining the kingdom's independence and stability. The Dutch East India Company (Verenigde Oostindische Compagnie) and the British East India Company vied for strategic advantage within Ayutthaya, and by the seventeenth century the Dutch East India Company was able to plant a commercial base in the capital. Both companies invested heavily in Siam, establishing manufacturing centers in Patani and Ayutthaya that employed both local and foreign workers, while the French invested in education and medicine. Codifying civil and criminal laws, Ayutthaya's rulers centralized their power over the kingdom's political, economic, and religious structures, making Ayutthaya an international power. In 1609 the first Siamese embassy was received at the Hague, a testament to both its commercial and political

strength. Ambassadorial delegations were sent to the major trading partners of France, Portugal, and England. Ayutthaya welcomed French ambassadors in 1685, 1686, and 1688, and Western visitors lauded the splendor and glory of the city evidenced by the three palaces, almost 400 temples, and fortresses. The capital grew to have a population of more than a million people before it was sacked by the Burmese in 1767.

Portugal's Colonial Cities

The Portuguese empire was one that encompassed four continents and thousands of miles. It spread across many cultures, but despite this they were able to leave a permanent mark wherever they went. Cities in Africa, Asia, and South America all bore similar Portuguese characteristics in architecture and government, unifying them with the mother country.

The establishment of trading posts and forts along the western coast of Africa was the beginning stages of what would become the Portuguese empire. Eventually, the Portuguese transitioned to building cities in the major ports where they traded, such as Macao, Goa, Luanda, and Bahia. Unlike the Spanish who built their cities atop previously existing ones, the Portuguese built their cities in areas where no city had existed before. This accounts for the nature of the cities, built in the same manner as cities in Portugal. Until the mid-eighteenth century the Portuguese constructed their colonial cities

with narrow, winding streets, and the houses were built extremely close together. This does not mean that the Portuguese were poor urban planners, but oftentimes the cities grew larger than had originally been planned, causing the outskirts to grow in an erratic manner. The proximity of the housing was often the culprit in the spread of disease and fire. In addition, the buildings were built in the Portuguese Manueline style, making them the most obvious reminder of the city's colonial status. However, there was not a total loss of the local culture, as many of the Portuguese immigrants were known to decorate their homes, both inside and out, with local stones and art. Finally, many of the cities were planned in a similar manner to Lisbon and Porto in that the important government and religious buildings were built high up in the hills in a defense position, while the commercial buildings were built below, or in the *baixa*.

Another major similarity among the cities of the Portuguese overseas empire was the establishment of Municipal Councils (*senado da camara*) and Holy Houses of Mercy (*Santa Casa de Misericórdia*). These two institutions had their foundations in the cities of Portugal and were thus transferred to the colonies as well. The purpose of the Municipal Councils was to administer the business of the colonies. Unlike the governors that came and went, the councils were a permanent fixture in the colonists' lives. It also gave wealthier city members a chance to gain elite status, as the core of the councils consisted of anywhere from two to six *homens bons*, or "worthy men," depending on the size and importance of the city. The councils also decided on important matters, such as the regulation of commerce. Superiors could not overturn the decisions of the councils, unless it came into conflict with a royal law. In addition, the councils also consisted of four councilors who were representatives of the professional guilds (masons, tailors, cobblers, etc.). Although from the artisan class, these men had the same voting rights as the other councilors in matters pertaining to the guilds, and they advised the council on matters such as the prices set by the various journeymen and master craftsmen.

While the Municipal Council was the administrative arm of the colony, the Holy House

of Mercy was the religious branch. Like the governors, the bishops were transitory, and so the Misericórdia, as well as the local church, were the stable religious figures in the colonial cities. However, many laymen served in this organization, usually from the elite. The Misericórdia was responsible for the charitable functions of the city. They ran hospitals, orphanages, and gave charity to the poor. Because of the impractical nature of giving these services to the entire populace, especially in regions with slaves, these services were normally reserved for the Christian population. In the beginning, the leadership was also determined to maintain "racial purity" among its members. However, this became impossible as miscegenation became more pronounced and the *mestiços* became more numerous. Also, members of the Misericórdia were not supposed to be members of the Municipal Council and vice-versa. By the eighteenth century this rule began to be overlooked and corruption grew along with the wealth in the empire. However, despite these shortcomings, this uniquely Portuguese institution aided colonists and provided a safe haven for many whose lives had fallen on disastrous times.

One thing that was not consistent throughout the empire was the treatment of the natives by the colonial government. In some instances, the natives were left relatively alone, in others, they were given strict European standards by which to live, and still others were somewhere in between. One example of an in-between model is that of Goa, India. The first governor of Goa, Afonso de Albuquerque, was careful not to interfere too much with the local Hindu customs and practices. However, he did highly encourage marriage between Portuguese men and Muslim widows. All of these couples received a house, land, a horse, and money. However, once the Inquisition was established in 1560, all converts were thereafter forbidden from participating in any Hindu ceremonies or rituals. Because of these actions, a unique Indo-Portuguese culture grew within Goa because the two cultures were allowed to flourish simultaneously. Indeed, the lack of Portuguese women in Asia caused the men to intermarry with local women, which created hybrid cultures in many of the cities. However, in many cases the colonial elites still

attempted to keep their families “white” by ensuring their daughters married white men, whose families were “pure of blood,” meaning lacking any Jewish ancestry.

The nature of Portuguese colonization meant that their imprint would last centuries. In fact, most of the cities that were once part of the Portuguese empire still retain their undeniable Portuguese character among the edifices of the city, as well as in the people themselves.

Islamic Centers in Southeast Asia

Although located on the far eastern end of the Indian Ocean zone, maritime Southeast Asia, consisting of present-day Indonesia, Malaysia, the sultanate of Brunei, and the southern provinces of Thailand and the Philippines, has been a part of the Muslim world for centuries.

Although little is known with certainty about the beginnings of the Islamization of this region, Southeast Asia’s contacts with the Middle East and India go back to pre-Islamic times. It is highly probable that Muslims from Arabia, Persia, and the Indian subcontinent all played a role in introducing Islam to Southeast Asia. The first indications of a political entity with a Muslim ruler were found in Samudra-Pasai, on the island of Sumatra, and can be dated to the late thirteenth century. But it is not until the fifteenth century that we have more conclusive evidence of an established Muslim state in Southeast Asia. Malay, Chinese, and Portuguese sources confirm that the ruler of the trading emporium of Malacca (Melaka) had converted to Islam before the 1420s.

From Malacca, Islamic influence spread throughout the Malay Peninsula, and by 1457 it had reached as far north as Patani. By the 1470s

there were Muslim rulers in Pahang, Trengganu, Kelantan, and Kedah as well. When the Portuguese conquered Malacca in 1511, Patani became the most important center of Islamic learning and political power on the Malay Peninsula. Between the 1580s and early 1600s Patani had the distinction of being a Muslim state ruled by a series of female sultans.

Scholars have suggested that in regard to the beginning of the region’s Islamization it is more appropriate to speak of adherence, whereby Islam is accepted alongside other religious practices rather than conversion in the full sense of the word. It is also important to be aware that the Islamization of Southeast Asia was not a uniform process but instead followed multiple trajectories.

On Java, the arrival of Islam is connected with the so-called Wali Songo, nine semilegendary holy men or saints probably of Middle Eastern or Indian origin. Their shrines have remained centers of pilgrimage until the present. The emergence of a string of Muslim sultanates along Java’s northern coast was to a large extent the work of these saints, who either associated themselves with established royal houses or became rulers in their own right. Demak, founded by a descendant of the Central Javanese Majapahit dynasty, was the first Muslim power of consequence on Java. Its main mosque functioned as the center of Islamic learning for Central Java from the early 1500s onward. Among the other Islamic centers along the northern coast were Japara and Kudus.

One of the Wali Songo, Sunan Gunung Jati, who is said to have come from Pasai, is associated with two Islamic centers in West Java: the sultanate of Banten and the town of Cirebon, where he is buried. In eastern Java, Islam spread from places such as Gresik, Tuban, and Surabaya. The latter two are also home to the shrines of two saints, Sunan Bonang and Sunan Ampel.

When Malacca fell in 1511, many Muslim traders moved to Aceh in northern Sumatra. This important trading place, where the main commodity was pepper, soon became the new Islamic power center of Southeast Asia. The sultans of Aceh quickly positioned themselves as the leaders of Malay opposition to Portuguese and, later, Dutch incursions. In addition, they

► MALACCA—MALAYSIA'S ISLAMIC STRONGHOLD

Strategically located on the Malacca Straits, which connects the Indian Ocean with the South China Sea, Malacca became the first Islamic power center in Southeast Asia. According to the *Sejarah Melayu* (*Malay Annals*) it was founded by Paramesvara, a descendant of the Sailendra dynasty of Palembang, and it was his son who embraced Islam around 1414, ruling as Sultan Iskandar Shah.

The significance of this event is considerable, because as Malacca's economic and political power grew, its distinct court culture, merging indigenous Malay features and Islamic elements of Arabic, Indian, and Persian origins, spread throughout the archipelago. One such element was

the replacement of the ruler's Sanskrit title of raja with the Arabic title of sultan. The Malaccan Malay dialect became Southeast Asia's lingua franca, used by local and foreign traders as their means of communication.

Malacca's political fortunes were short-lived; within a century from its emergence as the Muslim trading center in Southeast Asia, it fell in 1511 to the Portuguese. They were ousted in 1641 by the Dutch, who controlled Malacca until 1824 when it became part of British Malaya. Now one of the states in the Federation of Malaysia, it banks on its legacy of former Malay grandeur.

—Carool Kersten

became patrons of Islamic learning, establishing contacts with the main centers of the Islamic world: Mecca, Medina, and Istanbul. Aceh became known as the Serambi Mekkah (the Porch of Mecca), hosting a number of Muslim scholars of Sumatran and Indian origin who made seminal contributions to the development of a Malay Muslim literature. Proficient in both Arabic and Malay, figures such as Hamzah Fansuri (d. ca. 1600), Shams al-Din al-Sumatrani (d. 1630), and Nur al-Din al-Raniri (d. 1658) were instrumental in the introduction of mysticism and Islamic sciences, including Islamic law (Sharia). Another Acehese scholar, Abd al-Rauf al-Singkili (d. 1693), provided the first Quran exegesis in Malay as well as a host of other religious writings.

With the appearance of Muhammad Yusuf al-Maqassari (d. 1699) another line of scholar networks, connecting the Malay-Indonesian archipelago with the Middle East, emerged. After his studies in Arabia and Syria, he returned to Southeast Asia, dividing his time between his native Sulawesi (Celebes) and the sultanate of Banten. There he became involved in an anti-Dutch uprising led by Sultan Ageng that resulted in al-Maqassari's banishment to Sri Lanka and then South Africa, where he died. In the eighteenth century these networks were also sustained by other centers in Palembang, southern Kalimantan, and Patani, serving as conduits for the introduction of Islamic reformism.

Cross-cultural Contact and Trade Networks in Islamic Central Asia

The late classical era in world history witnessed the fragmenting of the Mongol empire, the fading of its last revived remnants in the fall of the domains of Timur Khan (Tamerlane), and the shift in global trade away from overland routes to sea routes that roughly paralleled (though was not necessarily linked to) the Mongol-Timurid collapse. But none of these factors, independently or combined, was sufficient to deter the vigorous overland trade and, with it, cross-cultural exchange within the Central Eurasian heartland. That heartland consisted of the area roughly east to west from northwestern China to the Caucasus and north to south from southwestern Siberia to northern Iran, with its trade network roots reaching down more than three millennia into the region's history. The shift to sea routes affected most immediately those states with ports of access to the world's

➤ ASTRAKHAN

The city of Astrakhan spreads over 11 islands amid the Volga River delta, which tapers off into the northern rim of the Caspian Sea. At this strategic juncture, it has long been situated at an important crossroads on the east-west trade routes connecting Europe and Asia. It has likewise functioned historically as a central point of contact between Russia to the north and Central Asia and the Middle East to the south. Astrakhan has long attracted visitors from far and wide, including the Moroccan Muslim traveler Ibn Batutta, who made mention of it in 1333 as a “duty-free” settlement. Merchants and missionaries from Greece, Persia, India, China, and elsewhere throughout Eurasia settled there to conduct their business.

Astrakhan’s multicultural makeup was a result of not only a significant decline in cross-cultural exchange via the overland routes in the post-Mongol period but also the fact that the rule of Astrakhan and its surrounding territory passed through the hands of various dynasties across the centuries. These dynasties included the Khazars (sixth to thirteenth centuries); Chingis Khan and the Mongols (thirteenth century); the Golden Horde (1227–1459), under whom it was destroyed by Tamerlane in 1395; the Tatars (1459–1556); the Russians via the conquest of Ivan IV (Ivan the Terrible) in 1556; the Torgkut branch of the Kalmucks, also known as Oirats, who took control over the city and its regions in 1630 after being forced from their Mongolian homeland; and finally full Russian control from the turn of the eighteenth century onward under Peter I (Peter the Great). The Ottomans as well as the Cossacks sought to take over its reigns in 1569 and 1670–1671, respectively, though without success.

Astrakhan’s predominant ethnocultural and linguistic base has been Turkic, Mongolian, and

Illustration of Astrakhan in the seventeenth century. (Rambaud, Alfred. The History Of Russia, 1897)

Euroslavic, while its religious foundations have largely been Muslim, Russian Orthodox, and Catholic. But its geographical and political significance helped create a much more varied linguistic, ethnocultural, and religious atmosphere. Early on, the Turkic Khazars had favored Judaism and Christianity, with strong ties to the Byzantine Christian world. The Mongols were mainly Tengrist and shamanist in orientation but maintained a policy of strong religious tolerance and hosted Buddhists, the Church of the East, Byzantine Christians, Muslims, Catholics, and others. The Golden Horde and the Tatars were Turkic Muslim, the Kalmucks were Mongolian Buddhists, and the Russians were Slavonic Orthodox Christians with strong roots in the Byzantine Greek tradition. Astrakhan’s ethnocultural, linguistic, and religious diversity has contributed to both healthy and vigorous cross-cultural exchange as well as periodic tension and conflict.

—R. Charles Weller

waterways. While it may have meant a decrease in the volume of certain exotic merchandise transported across Central Eurasia from outlying regions, such as China, India, Europe, and elsewhere, Central Eurasia itself remained, for the most part, landlocked. Therefore, the overland trade networks and, with them, the trade goods that had for long centuries and even millennia served to interconnect the region as a whole not

only remained intact but also continued flourishing, notwithstanding the usual ebbs and flows affected by as well as in turn affecting the shifting political, religious, and/or ethnic-cultural relations and balances of power.

Most notably among the political powers affecting the Central Eurasian trade networks within the late classical and early modern eras of world history would be the interplay of Ottoman

(1517–1914) and tsarist Russian (1552–1914) ambitions, with the Safavids of Persia (1501–1736), the Mughals of India (1526–1707), the Ming (1368–1644) and Ch'ing (1644–1911) of China as well as the three smaller kingdoms at the heart of the Central Eurasian web—Khiva (1515–1919), Khokand (1710–1876), and Bukhara (1785–1920)—also affecting the mix. Indeed, much of the trade was conducted by merchants in the hire of the various official courts, though plenty of private commercial exchange took place within these economic and political frameworks as well.

Attestations of vigorous ongoing trade and with it cross-cultural exchange across the region remained plentiful, such as that of the annual pilgrimage of Nogai herdsmen, with their synthesis of Islamic faith and seminomadic lifeways, delivering thousands of horses to the predominantly sedentary Russian Orthodox powers in Moscow in supply of the latter's military and other pragmatic needs. At the opposite end of the Central Eurasian trade networks, many of the horses that filled the stables of the Turkic Muslim Mughal rulers in India—surpassing quantities at times of 25,000 or more—were supplied by their Turko-Mongolian and Turko-Persian Muslim kin from their Central Asian motherland, with horses from the Kazakh steppe and Turkmenistan, together with those of the Nogai, being in large demand.

Other commodities exchanged across the post-Mongol Silk Roads network included lambs, goats, camels, various hides, furs, silk and other material, ready-made clothing, silver, gold, precious stones, cotton, honey, dishware and vessels, decorations, slaves (both adult and children), tools, weapons, and much more.

The trade networks involved merchants, moneylenders, border guards and customs agents, court and private treasurers, innkeepers, eateries, markets, craftsmen, herders, trappers, farmers, and many others representing a wide variety of ethnic, cultural, and political groupings, including Siberians, Russians, Bulgarians, Turks, Armenians, Tatars, Nogais, Kalmuks, Kazakhs, Kirgiz, Uighurs, Uzbeks, Turkmen, Tajiks, Altai peoples, Mongols, Chinese, Tibetans, Indians, Iranians, Khwarazmians, Bukharans, Cosacks, and many more.

While cross-cultural exchange flourished along the Central Eurasian trade networks in

the late classical and early modern eras, it would be a distortion of images to depict it all as harmonious and mutually beneficial. Religious, ethnic-cultural, and political tensions as well as economic competition were all part of the exchange or, as the case might be due to those tensions, the nonexchange. One can note here, for example, the way in which the Russian powers played the Buddhist Kalmuks against various Muslim Turkic peoples in the Ural-Volga region in the seventeenth century or the competition between the Bukharan and Khwarazmian neighbors to conduct trade with Russia, Siberia, and other areas.

Predominant or exclusive trade networks also tended to develop between differing ethnic-cultural and political entities, such as the Nogais monopolizing nearly all trade with Siberia in the sixteenth century or, conversely, the lack of any direct trade by Khwarazmian merchants with India or China in the sixteenth and seventeenth centuries. While the overall Central Eurasian trade network remained intact across the centuries, these kinds of various subnetworks continued shifting and changing in connection with the political, religious, and ethnic-cultural contexts in which they functioned and that they, in turn, reflexively affected and shaped. In this, the Central Eurasian trade networks continued serving as the primary vehicle for cross-cultural contact and exchange across the region in the late classical and early modern eras of world history.

Nobles and Commoners in Early Modern Europe

Throughout the early modern era, custom, lifestyle, and law in Europe distinguished nobles from commoners. Despite major alterations in the nature of the social structure, Europe remained rigidly hierarchical until the modern era. There was a general movement from a system of medieval orders based on function to a class system based on economic and social status, but an aristocracy based primarily on birth continued to remain at the top of society.

Medieval French society was divided into three estates, or orders of descending status: those who prayed, those who fought, and those who worked. The first estate was the clergy, the second was the nobility, and the third was the commons. Birth determined whether one belonged to the first two orders, as members of the nobility filled the most important offices in the Church. Because the social order rested on theological foundations, individuals rarely questioned the system or their situation within it. However, with the rise of commerce in the High Middle Ages, a new group within the third order, the rich merchants, began to complicate a social order based on function. Significantly, they did not appear to work with their hands. In addition, by the early sixteenth century the offspring of merchants (or even rich peasants) could afford a legal education. Degrees in civil and canon law became the passports to high offices in the Church or the government, and many of the latter carried with them noble status. Although these new nobles, called nobles of the robe, never attained the social status of the old warrior nobility, the nobles of the sword, the very existence of social mobility undermined the system of the three orders. Paradoxically, as members of society moved from one estate to the other, social distinctions within the estates solidified. This can clearly be seen in the middle classes consisting of merchants and craftsmen living in cities and towns. Their status was increasingly arranged into ranks determined by political authorities or guilds. For example, craftsmen were separated into a rigid hierarchy of masters, journeymen, and apprentices.

By the sixteenth century, European society moved from a system of orders defined by function toward a society defined according to social status. However, throughout the early modern era nobles and commoners were still defined by birth and legal privileges. Usually nobles were allowed exemption from certain taxes and were allowed privileges such as hunting rights or the right to bear arms and more lenient sentences for the same crimes. There were wide geographical variations, however, in the nature of the nobility throughout Europe. In particular, the size of the nobility varied widely. The nobility as a legal order made up between .5 and 2 percent of the population in western Europe and perhaps up to 10 percent of the population in parts of eastern Europe.

Nobility could be established by the recognition of peers as well as the law. This was the quality of honor, so cherished by the nobility. Whether legally noble or not, a noble had to live a noble lifestyle. For example, members of the English gentry, though not legally noble, were considered gentlemen if they owned a country estate and if their ancestors had refrained from trade for several generations. Land and leisure were considered essential attributes of nobility.

Noble self-definition did not remain static throughout the early modern era. Originally a warrior elite, the European aristocracy adopted the courtly values of etiquette and education in the seventeenth century. The centralization of the nation-state and the increasing use of professional armies rendered the warrior function of the feudal nobility obsolete. Kings such as Louis XIV at Versailles invited nobles to live with them in grand palaces, where they could compete with each other at court, not on the battlefield. At court the nobility sought honor and prestige, now seen as emanating from the king. The key to social success at court was self-control of both the body and the mind. The adoption of education and good manners by the nobility has been described by Norbert Elias as the “civilizing process.” Whereas before the seventeenth century the nobility partook of elements of popular culture, especially festivals and blood sports, the nobility began to set itself apart from the common people.

Commoners made up about 95 percent of the population. The commons was a varied group, containing from bottom to top vagrants, beggars, serfs, peasants, craftsmen, merchants, and professionals. With the exception of the very poor, most members of the third estate claimed privileges as ardently as the nobility. For example, the criteria for membership in guilds, confraternities, and city councils were as inflexible and stringent as for the nobility. The system of privilege, in which members claimed certain rights according to membership in a group, went largely unquestioned until the end of the eighteenth century.

In the social system of early modern Europe, one's place in society had to be displayed in the community. Sumptuary laws that indicated who could wear what were very common throughout Europe. Certain fabrics, such as silk, were reserved for the nobility by law. A noble who could not afford the outfit of a nobleman could honestly not call himself one. Lavish displays were not only expected but also necessary to preserve the social status of the family. Only at certain festivals such as carnivals could these social rules be relaxed. Here peasants might act like kings and men might dress like women, but it is unclear whether these actions confirmed or undermined the social order.

Nobles and commoners were also distinguished by diet. In general, peasants ate whole-grain bread, while nobles ate bread made from refined white flour. Also, the peasant diet revolved around grains and vegetables, whereas the noble diet included meat (the larger the animal, the higher the status). Nobles tended to drink wine, while commoners drank beer or cider. However, by the eighteenth century commoners gained access to many food items that were reserved for the nobility in the sixteenth and seventeenth centuries such as coffee, tea, and chocolate. In fact, coffeehouses served as public spaces where nobles and high-status commoners, or notables, could discuss philosophy and politics. This new domain where noble status mattered less than ideas would prove revolutionary.

By the eighteenth century, members of the commons had acquired almost everything that had originally distinguished the nobility. The

development of overseas commerce and the stock market in the seventeenth century blurred the line between income from land and income from investments, for both enabled one to live in leisure. The ability of individuals to invest in stocks enabled many to buy landed estates. Government offices were available to talented individuals, as education and good manners became widespread among the middle class. As these social distinctions faded in the eighteenth century, the nobility tried to make true ennoblement, granted by the king, less common. This in turn led to tensions that would surface in the French Revolution. The Industrial Revolution further rendered the social structure of the Old Regime obsolete as commoners gained the opportunity to become captains of industry. A system of classes replaced the system of legal privilege, but an aristocracy remains in the most democratic Western societies, where an elite few are often endowed by birth with substantial social and educational privileges.

Urban Growth in Europe

Europe's growing and dynamic cities were at the center of many processes that collectively brought about the modern world. In the early modern period, circa 1450-1770, cities contributed in crucial ways to the growth of state power and centralized administration, the expansion of overseas trade and empire, improving

► SAMUEL JOHNSON'S LONDON

Samuel Johnson (1709–1784) was one of eighteenth-century England's greatest literary minds—a critic, biographer, philosopher, essayist, poet, and lexicographer—and was likewise known for his keen observations of urban life in his beloved London. Though born in Staffordshire, Johnson spent most of his adult life in London, residing there from his arrival as a penniless writer in 1737 to his death in 1784. His experiences spanned the social spectrum and a wide range of literary, political, commercial, and professional circles, thus leaving him uniquely placed as an observer in a period that saw great urban growth and transformation.

Eighteenth-century London was admittedly smoky, filthy, crowded, germ-infested, and rank by modern standards. Yet the capital also continued to be the vigorous hub of social, political, and intellectual life and the wellspring of finance, trade, and fashion in early modern Britain. Historians believe that London's population at the beginning of the eighteenth century was about 650,000, and by the first census in 1801, London's population numbered some 900,000 people. Johnson himself witnessed urban growth firsthand, attesting to “a great number of new buildings in London of late.” Likewise, he was not unaware of concerns such as poverty, disease, and lack of work that affected the populace. While Johnson admittedly underestimated (at over 1,000) the number of Londoners who died each year of hunger, wasting, and other diseases, he was fully cognizant that they existed. He believed that the success of begging was overrated and sympathized with those who simply could not find work despite their best efforts.

Indeed, Johnson was an observant man with a keen eye for popular welfare and supported social reforms in many areas: charity, poor relief, the campaign to eliminate capital punishment, the abolition of slavery, and, lastly, debtor's prisons, as he believed that they led to idleness and waste. His peers remarked on Johnson's own frequent and generous charitable giving. James Boswell, his biographer and friend, recalled that Johnson “frequently gave all the silver in his pocket to the poor, who watched him, between his house and the tavern where he dined.”

Though often associated primarily with the tony neighborhood of Fleet Street and the elevated

Map of London, 1767. (Jupiterimages)

intellectual and social circles he frequented later in life, Johnson was an impoverished writer before attaining respectability and was still well acquainted with the London of the masses. He famously said of London: “You find no man, at all intellectual, who is willing to leave London. No, Sir, when a man is tired of London, he is tired of life; for there is in London all that life can afford.” Indeed, one of his first published works was the poem *London* (1738). He loved especially the vastness, endless variety, and intellectual opportunities that it offered. Boswell remarked that Johnson's “love of a London life was so strong, that he would have thought himself an exile in any other place.”

transportation networks and more integrated national economies, and the creation and distribution of new ideas. Despite the enduring importance of agriculture and rural life in 1770 and beyond, Europe's cities were vital motors of widespread social, political, and cultural change.

Most European urban areas were founded by the ancient Romans or during the subsequent medieval centuries; by 1500 Europe already contained over 150 cities of over 10,000 inhabitants and thousands of smaller towns. Such minor centers were usually encircled with defensive walls and served as service centers and markets for their rural hinterlands. After 1500, however, the number of European cities over 10,000 people more than doubled, reaching over 350 by 1800. Mediterranean Europe, especially central and northern Italy, was the most urbanized region in 1500, but by the eighteenth century northern and western Europe—especially Britain, the Netherlands, and Germany—contained as many large cities as or more large cities than Italy or Spain. About 5 percent of all Europeans lived in cities in 1500, but by 1750 over 12 percent of Britons lived in cities, and in Europe's most urbanized region, the Low Countries (modern Belgium and the Netherlands), almost 25 percent of the population was urban. Cities were unhealthy, beset by pollution, overcrowding, and frequent outbreaks of contagious disease, so urban growth depended on constant immigration from rural areas. City dwellers died sooner than Europe's rural population, but migrants were nevertheless continually attracted to cities by prospects of work and the hope of social mobility.

Urban growth during these centuries was not uniform; the most rapidly growing urban centers were those that served as capitals to strong and centralizing states. London and Paris, both important capitals, grew from under 100,000 people in the sixteenth century to over 500,000 during the eighteenth century; Madrid was transformed from a small town into a major metropolis when Philip II moved the Spanish court there in the 1560s; Vienna and Prague grew as centers of Habsburg administration in the Holy Roman Empire; Rome, Berlin, Stockholm, and Naples all grew as centers of administration; and most dramatically of all at St.

Petersburg, swampland on the Baltic was transformed into the Baroque capital of the Russian empire. Exceptions that prove this rule existed in the decentralized states of Poland and the Netherlands, whose capitals of Warsaw and The Hague, respectively, grew very little. Other cities prospered as centers of overseas trade and imperial expansion. Lisbon, Seville, and Antwerp grew through the profits of Spain's American empire in the early sixteenth century, and Amsterdam became the center of Dutch global trade in the seventeenth century. Capitals such as London and St. Petersburg that also served as centers of shipping and trade grew more dramatically than capitals such as Madrid or Rome that lacked ports.

Such large and growing urban centers had to be fed, clothed, and supplied with fuel, building materials, and the vast variety of luxury goods required by their royal courts and prosperous merchants. Provisioning large and growing cities thus promoted increasingly market-oriented agriculture and small-scale industry in their rural hinterlands. Urban merchants sold cloth produced on rural looms, ate food imported through gradually improving networks of roads and shipping canals, and burned fuel (coal in much of Britain, peat in the Netherlands, and wood elsewhere) imported from immediate or distant forests, peat beds, and mines. Europe's cities were markets that drew producers, merchants, and shoppers near and far into their orbits, connecting them to interurban and even transoceanic trade networks. Cities imported goods from America, the Middle East, Asia, and Africa and exported manufactures to overseas markets, especially the expanding European empires in America and Asia.

This demographic and economic growth made Europe's cities dynamic and innovative intellectual centers. From 1450 printing was centered in cities, where printers and booksellers determined what books were available to urban and rural readers alike. New forms of commercial theater in seventeenth-century London, Paris, and Madrid made possible the enduringly popular works of Shakespeare, Moliere, and Lope de Vega, while in Venice Monteverdi developed opera. From about 1650 coffeehouses flourished in London, Paris, and Amsterdam as spaces

in which the consumption of imported foreign goods facilitated the consumption of the new printed newspapers. By 1770 Europe's growing cities were cosmopolitan centers of trade, culture, ideas, and politics, the places in which one was most connected both to the outside world and to his own government. Early modern cities therefore prepared Europe for the nationalism, industrialization, and expanding imperialism of the nineteenth century.

New Cities—St. Petersburg

St. Petersburg, called by Fedor Dostoevsky (“the most artificial city in the world”), was built during the eighteenth century, starting in 1703, at the behest of Tsar Peter the Great, who wanted his new capital to be a “window on the west” for the Russian state. Peter also intended for his new city, located in the northwest of Russia on the delta of the Neva River and providing access through the Gulf of Finland to the Baltic Sea, to provide the base for a new modernized navy and to become Russia's most important trading port. In 1709 engineers completed the Upper Volga Canal, designed to link St. Petersburg with the interior of Russia as part of a wider network of water and roadways. In the nineteenth century railroad lines would provide additional transportation links.

Soon to be the northernmost city of its size in the world and constructed upon a marshy and inhospitable terrain, St. Petersburg was a difficult place to build in and to live in from the

start, and Peter had to command his *boyars* and merchants to do so under enormous duress. In 1712 he directly ordered 1,000 boyars and 1,000 merchants to build permanent homes in St. Petersburg. Owners of more than 3,500 “souls” were required to build not in wood but rather in stone. Forty thousand serfs were requisitioned each year to provide the labor. Many of them perished on the forced march to the distant site, and still more perished while working under the unhealthy and demanding conditions that prevailed. St. Petersburg began indeed as the imposition of Peter's will on the people and on the environment. Yet the commitment of the autocrat and his successors to St. Petersburg, especially Elizabeth and Catherine II, ultimately fulfilled Peter's vision: a universally admired European-style city, a “Venice on the Baltic,” famous for its canals and bridges, that became Russia's cultural, political, and economic center until the Bolsheviks moved the capital back to Moscow after the 1917 revolution. It has been said that Kiev is the soul of Russia, Moscow its heart, and St. Petersburg its mind, a nod to its premeditated origins and a tribute to its achievements. Throughout the eighteenth century, St. Petersburg became a lively cosmopolitan commercial and cultural urban environment.

Foreign trade with St. Petersburg began slowly due to the ongoing Great Northern War with Sweden (1701–1725) and Sweden's control of the Baltic. For some years, British and Dutch merchants preferred to continue to send their commercial ships farther north and around Scandinavia to the long-established port of Archangel, the port of choice of the England-based Muscovy Company since the sixteenth century. Peter used every means he could think of to reroute trade to St. Petersburg, including prize money, tax breaks, and outright decrees that increasing proportions of Russian trade had to pass through St. Petersburg and not Archangel. While at first control of shipping was in the hands of the foreigners, in 1716 Peter established the College of Commerce to develop and manage the Baltic trade, and gradually the Russians asserted their authority. St. Petersburg also became the site of one of the world's first commodity exchanges. In 1720 most British merchants and the Muscovy Company itself, soon to be renamed

➤ ALEXANDER PUSHKIN, *THE BRONZE HORSEMAN*

In 1833 Russia's beloved poet Alexander Pushkin published this paean, subtitled *A Petersburg Tale*, to Peter the Great and his vision for what would become St. Petersburg.

INTRODUCTION

There, by the billows desolate,
He stood, with mighty thoughts elate,
And gazed; but in the distance only
A sorry skiff on the broad spate
Of Neva drifted seaward, lonely.
The moss-grown miry banks with rare
Hovels were dotted here and there
Where wretched Finns for shelter crowded;
The murmuring woodlands had no share
Of sunshine, all in mist beshrouded.

And thus He mused: "From here, indeed
Shall we strike terror in the Swede;
And here a city by our labor

Founded, shall gall our haughty neighbor;
'Here cut'—so Nature gives command—
'Your window through on Europe; stand
Firm-footed by the sea, unchanging!'
Ay, ships of every flag shall come
By waters they had never swum,
And we shall revel, freely ranging."

A century—and that city young,
Gem of the Northern world, amazing,
From gloomy wood and swamp upsprung,
Had risen, in pride and splendor blazing.

the Russia Company, relocated to St. Petersburg. By 1722 with the end of the war, the majority of trade (exports of hemp, lard, tallow, pitch, leather, iron, linens, and sailcloth and imports of silk, wool, coffee, sugar, and wine) took place at St. Petersburg. In 1734 the Anglo-Russian Commercial Treaty confirmed Russia and its port at St. Petersburg as England's primary Baltic trading partner. Although subsequent trade treaties (1766, 1793, and 1797) were never quite as lucrative for Britain, St. Petersburg remained one of Russia's most important commercial partners overall for the remainder of the century. By the end of the eighteenth century, Germans were rivaling the British as the main trade partners of the Russians in St. Petersburg.

During the eighteenth century the Bolshoi Gostinny Dvor became the commercial center of St. Petersburg, boasting warehouses, shops, stalls, and eventually department stores. Bolshoi Gostinny Dvor continues as a major commercial venue to the present day. The Academic Printing House founded in 1727 was for many years the primary publisher in Russia of secular texts and one of the main publishers of scientific and scholarly works. It is now known as the Science

St. Petersburg, the economic, cultural, and political center of eighteenth-century Russia. (Library of Congress)

Printing House. The Admiralty dockyards early became a center for shipbuilding, starting with small craft, but by the end of the eighteenth century expanded to be able to produce large craft for both military and merchant purposes. Watercraft production at the Admiralty dockyards was crucial during the Crimean War (1854–1856) as well as during both world wars. In more recent times the dockyards have been important as a producer of icebreakers and submarines as well

as civil craft. In general, the dockyards helped to stimulate science, industry, and technology in St. Petersburg. Today it is known as the Admiralty Union.

From Tenochtitlan to Mexico City

When the Spanish conquistadors under Hernando Cortes first saw the capital of the Aztecs in 1519, they were suitably impressed. Tenochtitlan had about a quarter of a million inhabitants, probably four times as many as the largest Spanish city of the time. It appeared to float on a lake but was connected by three causeways to the shore. Suburbs ringed the shores of the lake and were home to many of the more offensive crafts, such as metalworking that produced smoke and odors. The city itself was scrupulously clean and carefully planned. The streets and canals were straight and converged on a central plaza where palaces and temples stood.

Tenochtitlan was dedicated to the god Huitzilopochtli. According to Aztec legend, a sacred

eagle had indicated where they should build their city around 1325. The original swamp was filled in with tremendous human labor. A lake surrounded the settlement, and the only way of entering was through causeways. Floating gardens provided space for growing corn, beans, and luxury items such as fruit and flowers. Because the city was dedicated to Huitzilopochtli, cleanliness was required as an expression of devotion. Neighborhoods were carefully and logically planned. Oftentimes, most people in a neighborhood were related and practiced the same trade. Control was through local lords who ensured that social order was kept. Neighborhoods were grouped into larger quarters, with local councils to govern them.

After the Spanish were forced to flee Tenochtitlan because of an Aztec uprising following Moctezuma's murder, Cortes enlisted the assistance of many Indian peoples who hated the Aztecs. He returned with an army and built a fleet of gunboats to control the lake in May 1521. After a ferocious siege that saw most of Tenochtitlan destroyed, Cortes took the city on August 13, 1521. At least 100,000 inhabitants had died from battle, famine, and diseases brought by the Spanish. Cortes proclaimed a new capital in Coyoacan, a few miles south. Soon, however, both Indians and Spaniards returned to Tenochtitlan's site to build new homes. In 1524, Cortes declared that the city would be the capital, with the name Mexico-Tenochtitlan.

The rebuilt city largely followed the plan of the old one. A grid pattern of streets radiated off the central plaza, known as the Zocalo. A cathedral, a royal palace, and governmental offices were located around the plaza. The conquistadors were especially interested in converting the Native Americans to Christianity and tried to wipe out anything that reminded them of their former religious practices. Consequently, they destroyed the pyramids and temples of the gods and dismantled any mosaics that had survived the siege.

Each ethnic group had its own segregated neighbors. The Spanish lived in an area completely encircling the Zocalo for ten blocks in all directions. The Spanish neighborhood was known as the *traza*. Aztec homes were located in the surrounding streets. Their neighborhoods

Map of Tenochtitlan, prepared for Cortes about 1524. (Bettmann/Corbis)

legally had equal status with the Spanish and were self-governing, under Spanish royal law. While the Aztecs had to provide service to the Spanish, they were free to follow most of the same trades as they had previously. Spanish authorities continued to fill in the lake, resulting in increased seasonal flooding. In the early seventeenth century, a drainage canal was constructed to channel the remaining waters from the lake.

Mexico City, as it became known, was the cultural, religious, and political capital of the colony of New Spain. Wealthy Spaniards and religious orders constructed magnificent palaces. The archbishop who controlled religious life in the colony had his home in Mexico City. Civil organizations, such as the Pontifical and Royal University, established their headquarters in the city. As the Spanish population grew, the traza could no longer hold them. They began to displace the Indian population, who were forced to move to the suburbs on the lake shores. A large public garden, known as the Alameda, was created in the early seventeenth century, further displacing Indian families. The equality between the ethnic groups began to diminish, and the natives were relegated to the less desirable locations as time went by. Even as slum neighborhoods grew, the city became more spectacular. Riches from mining and commerce poured into the city. Wealthy merchants and nobles built new palaces. By the end of the seventeenth century, Mexico City was the wealthiest and most important city in New Spain and probably in the entire Spanish empire.

British Colonial Cities in America

American colonial cities were conceived as physical manifestations of the transfer of civilization from the Old World to the New World. Cities were the counterpart to the exploitation of the natural resources of the New World and facilitated the export of wealth to Britain. Although modeled on British cities, the conditions unique to colonial life ensured that the new cities would be different. Whereas European cities had developed slowly over many centuries, colonial cities quickly assumed important political and economic functions. However, regional differences fostered varying urban cultures.

British American cities were exceptions within a landscape that was predominantly rural and agricultural. By 1770 only about 8 percent of the population lived in urban environments of more than 2,000 inhabitants, and five years later estimated populations for leading British American cities were Philadelphia, 40,000; New York, 25,000; Boston, 16,000; Charleston, 12,000; and Newport, 11,000.

In contrast, before its conquest by Cortes's army, the Aztec center of Tenochtitlan held an estimated 500,000 inhabitants. Yet the small size of British American cities belies their political, economic, and cultural importance in colonial life. As cities were the transfer points of goods and ideas going both ways across the Atlantic, they naturally had a leading role in fostering standards of culture.

New Amsterdam, originally a Dutch settlement, became the English colony of New York City in 1667. (Bettmann/Corbis)

➤ GENTEEL CULTURE AND THE CITY

Across the North American colonies, cities were bastions of transplanted European ideas, fostering genteel culture. Gentility meant the cultivation of refined taste and often implied an elevated moral stature. It was originally a term of praise and was limited to describing wealthy landowners—the gentry—and the provincial elite, suggesting the authority that came with high social class. Gentility was associated through elite education with emphasis on Greco-Roman languages, literature, and history. The middling class participated in genteel endeavors by the time of the American Revolution.

In the eyes of Europeans and some Americans, colonial culture was deficient. The adoption of British taste was a way for elite colonists to establish their authority and attempt to create a civilization on par with that of the British. Although not an exclusively urban phenomenon, genteel culture was eventually pursued vigorously by city merchants. Genteel taste was manifest in the demand for many types of material goods supplied by urban artisans and builders who were valued for their elegant adaptations of British styles.

Architecture and decoration in the commercial cities were among the most tangible manifestations of imported British taste. The construction and furnishing of an elegant home was a significant marker of gentility. Wealthy merchants employed builders to erect mansions and townhouses in cities up and down the Atlantic seaboard as physical expressions of their cultivated sensibilities. Owners furnished these homes with expensive items imported from Britain or handcrafted colonial works imitative of British styles. The commercial nature of colonial cities facilitated the dissemination of British taste through the importing and selling of books, pamphlets, and every variety of material good. In this way, material objects helped create a relatively unified Anglo-American identity.

—Paul Ranogajec

Colonial cities provided plots of cultivable land for the settlers. They were low scale and relatively homogenous socially and economically compared to European cities. This is also true relative to many Iberian cities in the Americas, where there were sometimes large gulfs

between classes. Spanish city building was controlled by the Laws of the Indies that standardized construction and settlement. The British colonies had no such overarching organization. Still, for the sake of expediency, many British cities, including New Haven, Philadelphia, and Savannah, adopted a grid plan similar to the Spanish cities.

Commercial activity and centralized imperial administration were the primary functions fulfilled by colonial cities. They were nexus points in a transatlantic economy connecting North America, the Caribbean, western Africa, and Britain. Cities, however, had other important functions. They provided the rural population with specialized crafts and other services that could only thrive in an urban economy. Some cities were founded with a specifically religious intent. The Massachusetts Bay Colony, led by Puritan reformer John Winthrop, established Boston in 1630 as a religiously sanctioned “City upon a Hill.” Newport, Rhode Island, was founded in 1639 by religious dissenters as a safe haven from the Anglican Church and Puritan orthodoxy. Philadelphia (1682), planned on the largest scale of any new city since ancient Roman times, was dedicated to religious tolerance by the Quakers.

Cities were most prosperous and numerous in the New England colonies, where intensive commercial activity reigned. The Puritans who settled this region sought religious reforms and economic advantages. They instituted rigid social structures to promote stable urban life. Previously divided plots of city land were sold to newcomers, and space was set aside for the town’s meetinghouse, which served religious, social, and administrative purposes. Northern cities were populated by merchants, traders, and craftsmen, resulting in a relatively affluent society. Goods from across the colonies and from the West Indies and Britain passed through the hands of New England merchants, making them an essential part of the colonial economy.

In the Middle Colonies, cities were more socially diverse as a result of the competing land claims by various colonizers, including the Dutch and Swedes. New Amsterdam, claimed for the Dutch in 1626 and renamed New York by the British in 1664, was originally a fortified military outpost and developed without formal

plans. Small canals were created in Manhattan so that New Amsterdam physically recalled its European predecessor. New York soon grew into a major port city and flourished under British control. Nearby Philadelphia was a generously scaled religious utopia, a holy experiment for the benefit of Quaker reformers and religious dissenters under the direction of William Penn. Penn's city boasted a grid plan 2 miles (3.2 kilometers) wide with broad avenues and large squares to enhance the beauty and healthiness of the city. It developed a prosperous merchant class and established a cultural importance rivaling Boston's.

The Chesapeake region of the South, encompassing Virginia and Maryland, was the first to be permanently settled by the British. Unlike Puritan New England, social mores were less rigid, and the population was less urban. The geography accommodated larger plantations than were possible farther north. Jamestown, Virginia, was the first permanent British settlement, although its swampy, isolated geography could not sustain urbanism. Williamsburg (1698), on more conducive ground, was eventually established as Virginia's colonial capital, while Maryland developed several important commercial cities, including Baltimore and Annapolis.

Southern colonists lacked the religious zeal found in the North. Few cities of prominence

developed there. Social and economic organization in the South hinged on the rural plantation system, which was virtually unknown in the North. Instead of urban centers, southern planters developed private shipping networks along the rivers that fed their plantations. In contrast to the North, the region developed a strong export economy based on staple products. Charleston (1690) was for a long time the major urban exception, prospering because of its excellent harbor location.

■ Introduction: Hierarchies and Colonial Relationships

The political and economic transitions of the early modern age necessitated wide-scale social reorganization. Centers of power and hierarchical organization within societies around the world shifted due to political or economic reorganization. In Europe and North America the realignment of power grew from political reorganization, often coupled with revolution or rebellion. Nevertheless, one could argue that the most dramatic reorganizations happened in the context of conquest and colonization. The Ottoman empire, for instance, established a new ruling elite as it spread across Anatolia (modern Turkey) and the Balkans after

the conquest of Constantinople in 1453. Not only did the conquest change the social structure as it instituted political dominance in the areas absorbed into the empire, but it also changed the balance of power in western Asia and eastern Europe. In a similar fashion, as the British East India Company gradually conquered or otherwise absorbed much of South Asia, the company irrevocably altered the indigenous power structures, notwithstanding its practice of ruling through indigenous intermediaries. Other conquerors, notably the Manchu who founded the Qing dynasty, gained the allegiance of many of the Chinese intellectual elite when

they actively perpetuated the traditional bureaucratic meritocracy present in China for centuries before their conquest. On the other hand, internal conquest also alters internal relationships, as when the Tokugawa unified Japan in the late sixteenth century, entering into a new and sometimes fragile relationship with Japanese peasants. Just as the indigenous people above were reorganized hierarchically after conquest or colonization, sometimes new (or creole) classifications of people emerged. An instance of this occurred when the Dutch relocated a group they called *Mardijker* to Batavia, thus incorporating them into a new social organization. Indeed sometimes, as shown in the entry about race and class in Latin America, the new classifications of people came from genetic blending rather than relocation, although the forced relocation of Africans gave rise to new communities in areas such as Belize. In these instances, revised hierarchical organization was literally born. And of course, the destabilization of culture did not depend entirely on armed takeover, as we see in the entry of the cultural impact of the Portuguese in Asia, but the disparity in power did cause destabilization of the existing hierarchies. Many factors influence status in societies, and all of these factors can have a destabilizing impact on the existing power structure.

—Carolyn Neel

The Ruling Institution in the Ottoman Empire

A visitor to the Ottoman palace in the sixteenth century would be entering the administrative center and the imperial household of a major power of the early modern world. By this time, the Ottoman state had transformed from a small seminomadic frontier principality in Anatolia (modern-day Turkey) into a multiethnic and multireligious empire controlling territories in North Africa, the eastern Mediterranean, the Arabian Peninsula, Anatolia, southeastern and central Europe, and the Black Sea region. This visitor, perhaps a diplomatic representative like the Habsburg ambassador Ogier Ghiselin de Busbecq, would be taken to the imperial council hall presided over by the grand vizier. Here the

visitor would meet the viziers who were responsible for military and political matters, the chief judges in charge of judicial matters, the treasurers who directed the finances, and the chancellor. Apart from this highest executive body of the empire, the palace also had the residential quarters of the sultan, where he lived with his household “like a pearl hidden in an oyster shell,” as described by a sixteenth-century Ottoman historian. Our visitor could not visit there because it was restricted to outsiders, even to the grand vizier. Seclusion played an important role in defining the power relationship between the sultan and his ruling elite.

This particular organization of the Ottoman ruling establishment was a part of the imperial project of Sultan Mehmed II (r. 1444–1446 and 1451–1481). Through his military campaigns in Anatolia and the Balkans, including the conquest of the Byzantine capital of Constantinople in 1453, Mehmed II tried to establish unified rule in a region that had been politically fragmented for centuries. He was also determined to establish a more centralized authoritarian rule vis-à-vis powerful groups among the Ottoman ruling circles. To increase his power against prominent Anatolian families, Mehmed II created a new elite that did not have a significant power base of its own and thus had less possibility to challenge his authority.

This new elite consisted of male and female members of the sultan’s household. A majority of the male members (*kul*) were recruited to the palace by being subject to a tax levy known as the *devshirme* (“gathering”). These were mostly the sons of Christian peasants from the Balkan provinces who were taken from their families when they were 8 to 19 years old. They were converted to Islam, learned Turkish, and trained for military or bureaucratic posts in Istanbul. This system must have been painful for many children and their parents, but it also allowed for high social mobility. After having completed their education, these young men could rise to some of the highest positions in the empire, including the grand vizierate. Ottomanization did not erase earlier memories, but ethnic solidarity played an important role in palace life. This was an elite whose members were united through their loyalty to the sultan while keeping their

➤ BUSBECQ, *TURKISH LETTERS*

Ogier Ghislen Busbecq (1522–1591) visited the Ottoman empire as a Habsburg ambassador from 1555 to 1560 and published his observations as a series of letters. Here Busbecq praises the *devshirme* system and what he perceives as meritocracy in the Ottoman system of appointments. We must note that although soldiers and officials with a *devshirme* background held important posts in the empire, there were also other members of the ruling circles who were from families of hereditary landowners and religio-administrative cadres.

“In all that great assembly no single man owed his dignity to anything but his personal merits and bravery, no one is distinguished from the rest by his birth, and honor is paid to each man according to the nature of the duty and offices which he discharges. . . . The Sultan himself assigns to all their duties and offices, and in doing so pays no attention to wealth or the empty claims of rank, and takes no account of any influence or popularity which a candidate may possess. . . . Those who hold the highest posts under the Sultan are very often the sons of shepherds and herdsmen, and so far from being ashamed of their birth, they make it a subject of boasting.”

In the following excerpt, Busbecq praises the janissary standing army and appreciates their discipline. Ottomans displayed their army to ambassadors in order to impress them with their military power, especially their command of highly disciplined centrally trained soldiers in good order.

“What struck me as particularly praiseworthy in that great multitude was the silence and good discipline. There were none of the cries and murmurs which usually proceed from a motley concourse, and there was no crowding. Each man kept his appointed place in the quietest manner possible. . . . The most remarkable body of men were several thousand Janissaries, who stood in a long line apart from the rest and so motionless that, as they were at some distance from me, I was for a while doubtful whether they were living men or statues, until, being advised to follow the usual custom of saluting them, I saw them all bow their heads in answer to my salutation.”

—Asli Niyazioglu

Source

Ogier de Busbecq, *Turkish Letters*, translated by Edward Seymour Forster (London: Sickle Moon Books, 2001), 39–41.

diverse backgrounds as Albanians, Bosnians, Serbs, or Circassians. The female counterpart of the *kul* was the institution of the harem. Young female slaves, mostly captured from the Mediterranean and Black Sea regions, were brought to the palace, where they were also converted, learned Turkish, and received palace education. Some of these women stayed at the harem as servants or concubines of the sultan. Others were married off to high-ranking officials, mostly those with *devshirme* origin, and thus took part in the making of the Ottoman elite.

The Ottoman provincial administration was also shaped by the sultan’s centralizing power. Provincial elite mostly consisted of officials who received the right to collect taxes in return for military service (*timar*). They exercised executive power over their lands, but compared to the medieval European feudalism there were significant checks to their power: the lands were

state-owned, their posts were not automatically inheritable, and they were subject to rotation. Moreover, they lacked judicial power. The state assigned judges (*kadis*) to its provinces, who along with the professors of law were members of the religio-administrative cadre (*ilmiyye*). This separation of legal and executive powers gave the state more control over the ruling circles. The separation of powers also aimed to protect the subjects of the empire against the abuses of state officials. An injured peasant could complain about a judge to a timar-holder or about a timar-holder to a judge or could take his case to the attention of the sultan. Such complaints as well as many other provincial affairs were meticulously recorded and preserved in the archives. They give us a rich portrait of the complex relationship involving the central state, provincial ruling circles, and subjects of the Ottoman empire.

Ottoman ruling institution, especially the provincial administration, experienced significant changes in the late sixteenth and early seventeenth centuries. A major change took place in the composition of its army and methods of tax collecting. The Ottoman army consisted mainly of the central army of salaried soldiers, including the janissary infantry and the provincial cavalry of the timar-holders. In the late sixteenth century changes in military technology required more standing soldiers centrally trained to use firearms. As the need for the provincial cavalry decreased, the Ottoman state increased the number of janissaries and transformed the provincial administration from timar to the tax-farming system. Officials were appointed to collect taxes and provide the state with cash for the salaries of the soldiers. Thus, by the end of the eighteenth century an important group among the Ottoman elite, the timar-holding cavalry, had almost disappeared. This transformation is an example of how the Ottoman ruling establishment was able to transform itself drastically in response to changing times from the mid-fifteenth century to the mid-eighteenth century.

White Town and Black Town— Madras and the Coromandel in South India

In the early 1600s, the British East India Company began to relocate the center of its commercial operations from Southeast Asia to the southeastern coast of India (known as the Coromandel). In

Masulipatam, the chief port of the diamond-rich kingdom of Golkonda, the British first attempted to establish a factory, or trading post. Masulipatam was not only a major market for diamonds, but the nearby villages of the Krishna-Godavari Delta were filled with weavers specializing in the production of high-quality cotton textiles. Unfortunately for the English, their commercial tryst with Masulipatam did not work out. The Dutch were hot on the heels of the English, also interested in the Coromandel Coast, and they bribed the local Mughal governor to cause trouble for the English, whose warehouses were ransacked and merchants chased away.

Thomas Day, a British East India Company merchant, took the initiative during the next few years to obtain a land grant farther down the coast, where the English began to build a fortified base of their own in 1639. Rather defiantly, Day and his colleagues named the place Fort Saint George, but very early on in their exchange of correspondence with their superiors in London, they referred to the fort as White Town and the neighboring Indian village of Chennaipattanam as Black Town. The entire settlement eventually became known as Madras. During the latter half of the seventeenth century, Fort Saint George developed into a massive, state-of-the-art fortification, while Black Town quickly grew into a burgeoning city almost as large as London, with a garland of bustling suburbs.

When the English first began to develop Madras in the 1640s, they were still concerned by their experiences at Masulipatam, and their attitude was decidedly defensive: they wanted to trade with India, but they craved the idea of security represented by high stone walls and segregated spaces. All of the Portuguese settlements in India, the English may have reflected, were both fortified and segregated. The fort-town arrangement was a common feature of early modern commercial outposts, but it was not without precedent in the Indian cultural context. Dividing cities into ethnic neighborhoods was a longstanding practice in South Asia, and in southern India many cities had long been divided into a fortified sector and an adjoining *pettah*, or bazaar.

Madras was much bigger than White Town and Black Town. For more than a century before the arrival of the English, there had been

a substantial renegade Portuguese town, São Thomé, situated 6 miles (10 kilometers) south of where Fort Saint George would be built. This settlement had long been divided into an Indian Christian quarter along the shore, a fortified Portuguese neighborhood, and an Indian quarter lying slightly inland and arranged around a large temple complex. Over the course of the eighteenth century, São Thomé was incorporated into the ever-expanding metropolis of Madras, as were several suburbs along the Coum River, settled by Telugu-speaking weavers who had migrated to the coast to work for the East India Company. Still another quarter of the city was built up by the Muslim rulers of the Wallajah dynasty, staunch allies of the English, who moved their court from Arcot to Triplicane, well within range of the protective guns of Fort Saint George. Some of the city's suburbs, however, were developed by the English, who sought an escape from the hot sun and brackish water of the fort and the crowds of Black Town. European residential areas sprang up in Egmore, Choultry Plain, and also at Saint Thomas Mount, an ancient Christian pilgrimage center located several miles inland near a low range of hills.

The fort-town format of White Town and Black Town was repeated at other European enclaves that grew up along the Coromandel Coast after the English founded Madras. At Pondicherry, the French quarter—the Ville Blanc—was surrounded by the sprawling Ville Noire, itself divided by religion and ethnicity. A canal divided European Pondicherry from the Indian city, while the houses of the French residents clustered under the guns of Fort Louis. A similar arrangement, on a smaller scale (without canals), existed at the Danish colony of Tranquebar and at the Dutch outposts of Sadras and Negapatam.

Wherever the new style of colonial city emerged, Europeans and Indians struggled with the problem of adapting to each other's civic institutions. The English at Madras, for instance, quickly learned that Black Town could not be managed like an English village but at the same time could not be run like a typical southern Indian village. In the seventeenth century, the administration of Black Town was carried out through the *dubashes*, or official Indian interpreters, attached to the governor's staff. These

A Plan of Fort St. George and the City of Madras, by Herman Moll. (Salmon, Thomas. *Modern History: or, the Present State of all Nations*, 1739)

individuals worked through the Heads of Castes, a body representing all of the different ethnic minorities and occupational classes of Madras, most of whom had their own streets and neighborhoods. The imposition of taxes, local laws, and town management were worked out, for the most part, through negotiations among the caste leaders, although sometimes disagreements led to bitter conflicts, thus forcing the English to intervene in Black Town's affairs. For the most part, however, the English preferred to let Black Town's leaders bear the burden of administering and policing the city.

White Town was never entirely European, for a few Indian merchants always lived there along with hundreds of servants working for English households. Nor was Black Town ever entirely Indian, for there were always at least as many Europeans living there as in White Town. By the early eighteenth century, 100 Black Town houses were listed as European-owned, and a large number of discharged English soldiers opened taverns and shops in the Indian quarter. Over time, the European residents of Black Town demanded and received more of a say in how the city was run; all of the traditional Indian ways of doing things were retained but augmented by

new practices, such as a municipal water supply, a scavenger to clean the streets, an English-style mayor, a town council, a municipal court, and eventually a Crown-appointed sheriff to make arrests and prosecute criminal cases. Some of these changes were an attempt to impose order on the Indian inhabitants, but many reflected the need to make the English residents answerable to the same laws that governed those who lived inside the walls of Fort Saint George.

The Chinese Examination System—Progress and Abolition

In the course of the 200 years that followed the Manchu conquest of China in 1644, the Qing dynasty (1644–1911) gradually built up a bureaucratic meritocracy by imitating the institutions and practices of the Ming dynasty (1368–1644) that the Qings had recently ousted. This bureaucracy, with its formal civil service examination system, represented the apex of China's state-sponsored education. During these two centuries the Chinese meritocracy also became a part of an "oriental mystery" observed and admired by European travelers and missionaries and that, through their reports, influenced Enlightenment thinkers. Ironically, however, while Europe and the United States subsequently adopted the practice of examinations in constructing their modern civil service bureaucracies during

the nineteenth century, the Qing dynasty was forced to abolish the traditional examination system in 1905 because Chinese critics believed that it had contributed to the collapse of the Chinese empire in the face of Western assaults and humiliation.

In order to consolidate Manchu power over China, the first Qing emperor, the underage Shunzhi (r. 1644–1661), followed the advice of Dorgon, his uncle and regent, to continue the policy of "using the Chinese to rule the Chinese." This strategy had been effectively established by Nurhaci, the founder of the Manchu dynasty, who had initially employed it to impose a strong Manchu state in northern China. In 1644 the young emperor rededicated the Temple of Confucius by bestowing the honorary title of duke on Kong Yunzhi, the sixty-fifth direct male descendant of Confucius, thereby showing his reverence for China's greatest sage. In 1645 while granting the posthumous honor of "Most Accomplished and Sacred Ancestor of Literary Education" on Confucius, as previous emperors had often done, Shunzhi ordered his dynasty's first set of provincial examinations to be held throughout the empire and according to rules that had prevailed during Ming times.

From the examinees 1,428 qualified candidates were selected, and the following spring they gathered in Beijing, the new Manchu capital, to participate in the first national examination. Subsequently the emperor awarded the degree of advanced scholar to 400 competitors. The positive response of the newly conquered Chinese people to the examinations encouraged the emperor to reorganize the imperial academies and restore government-sponsored schools in most of the provinces and counties throughout the 1650s.

The success of Emperor Shunzhi encouraged his successors Kangxi (r. 1661–1722), Yongzheng (r. 1723–1735), and Qianlong (r. 1736–1795) to gradually transform the Manchu militaristic court into a Chinese-style meritocracy. On the one hand, these Manchu rulers allied themselves with Mongol tribal chiefs in order to secure the empire's borders and to suppress the regional resistance of various claimants to the imperial throne of the deposed Ming dynasty. On the other hand, they gradually attracted increasing

numbers of Chinese scholar-officials to serve the imperial bureaucracy. Although initially unable to share real power with their Manchu counterparts, Chinese scholar-officials introduced literacy to their Manchu superiors and, to some extent, enabled the central government to counterbalance the warlordism of the Manchu and Mongol military commanders stationed along the empire's borders. The three emperors consistently demonstrated to their Chinese subjects a propensity for befriending and respecting Confucian scholars and an aptitude for traditional Chinese arts, especially calligraphy and poetry. Responding to the emperors' sincere adaptation to Chinese culture, Chinese intellectuals quickly accepted the Manchu emperors as legitimate rulers who had obtained the Mandate of Heaven.

During the eighteenth century the Qing dynasty masterfully operated a meritocracy system that required provinces and counties to allocate tax revenues to government-sponsored schools. The Qing assigned education commissioners to the provinces to supervise the recommendation process, in which the commissioners worked with provincial governors to nominate students to the expanded Imperial Academy. Some were selected by reason of their being awarded the degree of qualified candidate from a provincial examination, some were recommended because of their descent from 13 historically renowned Confucian scholars, and some were simply allowed to move up because they had become aged or sick after failing to pass the local examinations for a period of more than ten years. After studying in the academy for a certain period of time, often three years, graduates were either assigned to specific civil service positions or allowed to enjoy honorary titles without any specific responsibilities. Government-sponsored education therefore significantly broadened the social basis of Chinese support for and obedience to the Manchu rulers.

The Qing civil service examination followed closely the mechanism and procedures of the Ming system. It became routine for a county to offer an annual examination and award the degree of talented scholar and for a province to offer a triennial examination and award the degree of qualified candidate. The national examination in the imperial palace at the Forbidden City was

Civil service exam under Emperor Jen-Tsung, from The Lives of the Emperors of China, Qing dynasty, seventeenth–eighteenth century. (Bridgeman-Giraudon/ Art Resource, NY)

regularly held in the fall of the year after the provincial examination, and the emperor himself conferred the degree of advanced scholar on the most successful competitors. A total number of 406 advanced scholars were recognized in 1730, the highest number on record, and 96 were named in 1789, the lowest on record. Thereafter the degree was offered to 1 out of about 20 competitors. The Eight-Legged Essays, which demonstrated an examinee's knowledge of Neo-Confucian interpretations of the Four Books and Five Classics, remained the major component of the written examination; however, a standardized multisection examination also tested a candidate's ability to draft official documents, analyze policy issues, formulate legal opinions, and compose poems. The Qing examination system also adopted most of the Ming regulations that had been drafted to keep the examinations honest and fair. Some examinees complained that they were treated like criminal suspects when going through the strip search and other harsh procedures during examinations.

➤ CRITICS OF THE EXAMINATION SYSTEM

Gu Yanwu (1613–1682), a scholar who lived during the period of Ming decline and the ascension of the Qing, was one of the most outspoken critics of the Ming examination system. He criticized the system because it disallowed inclusion of any reference to historical events after the Qin dynasty (221–206 BCE) in the educational curriculum and the examinations. The following is an excerpt from Yanwu's *Diary of Learning*:

“[In the golden years of the early Ming dynasty,] when the Song’s dynastic glory was still the recent memory, Scholar Qiu Wenzhuang pointed out that some Advanced Scholars, ranked on the top of the Public Bulletin of Examination Results, knew nothing about the catalogue of the Official History, about the timetable of the past dynastic successions, and about correct formation of Chinese characters. They studied only the materials published by the Eighteen Houses, [from which the examination materials were officially published authorized by the imperial examination board]. After reading them for three to five years, they got lucky and climbed to the very top of the Bulletin, and, overnight, became the peers of the estab-

lished scholar-officials. As to literary elegance and military skills, they had abandoned them just like a horseman throwing away his whip. Alas. Today, the Eight-Legged Essays are flourishing, but the Six [Confucian] Classics are being neglected; the Eighteen Houses are glorified, but the twenty-one Histories are abandoned.

. . . I knew one or two gifted young students, when I was myself young, who were willing to study the unauthorized classics and to contemplate history. For doing so, they caused clashes with their fathers and teachers, who blamed them for not focusing on studying the correct textbooks, and cursed them for their not being able to have successful careers in the future. This is what I mean by saying that an adult pursuing only immediate profit is a stupid person.”

However degrading, the examination system was well received by most Chinese commoners, especially struggling examinees from humble backgrounds who intended to move up socially by the only ladder available.

Some of the holders of the advanced scholar degree were designated to serve in a county magistracy or an equivalent office. However, most were assigned to be senior editors of Hanlingyuan, the Academy of Literary Excellence, responsible for collecting, compiling, and collating the Confucian Classics, the official histories, and the literatures of renowned writers throughout Chinese history, or to be ranked educators, teaching in the Imperial Academy. The Manchu emperors did not entrust real governmental powers to Chinese scholar-officials until the mid-nineteenth century, when the Manchu elite military, the Eight Banners, appeared unable to stop Western intrusions or to crush the Taiping Rebellion (1850–1864). Therefore, while

an increasing number of degree holders were produced by means of the provincial and capital examinations during the eighteenth century, most of them eventually lived in local communities, devoid of official power but respected by the people for their knowledge and wisdom and trusted by the residents for their leadership in arbitrating or mediating local disputes. Although largely lacking true governmental authority, they played indispensable roles in constructing social order and harmony for the Manchu authority.

The Chinese meritocracy, especially the examination system, impressed European travelers, Christian missionaries, and Enlightenment philosophers throughout the early modern period. Though disagreeing with one another on the nature and meaning of Chinese absolutism, they admired what they thought to be a meritocracy in which honorable literati were able to rule an immense Chinese empire. To English gentlemen, Chinese scholars and scholar-officials actually

possessed the highest dignity in the state by reason of their effective administration of justice and ability to maintain social tranquility. They therefore respectfully termed these Chinese scholar-officials “gentry,” seeing in them oriental counterparts to the backbone of the English legal, social, and parliamentary systems. The Chinese practice of competitive examination, through the consistent advocacy of Western writers in the seventeenth and eighteenth centuries, was gradually translated into a component embodied in the European and American civil service systems during the nineteenth century.

While Western observers were praising the Chinese meritocracy, however, some Chinese intellectuals of the early Qing period began to question the validity of the examination system. Reflecting on the fall of the Ming dynasty to the alien Manchus, they criticized the disgraceful roles that the scholar-officials had been playing in sustaining Manchu imperial despotism. In the minds of radical critics, state-sponsored education overemphasized Neo-Confucian dogmas centered on the concept of “li,” or the patterns of the natural world. Not only did they deviate from the original and authentic teachings of the Confucian classics, but this aberration was also undermining the values of applied science and technology that could be used to counter Western intrusion. The standardized examinations were increasingly being reduced to a lifeless rhetorical puzzle, as witnessed in the Eight-Legged Essay format. And the meritocracy in operation was producing domestic slaves for the private households of the emperors while failing to criticize and thus balance the imperial authorities.

These criticisms did not get a warm response from Chinese intellectuals until the mid-nineteenth century, when a series of Chinese defeats at the hands of European powers within the period of a half century weakened both the Manchu rulers and the Chinese cultural elites. While most scholar-officials in power dreamed of reforming China by revitalizing Confucianism and consolidating it as the foundation of the state, the combined effort of struggling scholars within the traditional Chinese educational system, with their counterparts educated by missionary schools in China and in overseas colleges and universities, finally forced the Qing

authority to abolish the examination system in 1905. However, the people’s faith in meritocracy, especially their trust in fairness and equal opportunities represented by a reformed examination system, remained and has continued to be a crucial aspect of the sociopolitical life of Chinese all over the world.

Subjugating Japanese Peasants—The Tokugawa Period

Most scholars regard the Edo, or Tokugawa, period (1603–1867) to have been a time of remarkable peace and stability. The Tokugawa shogunate had effectively cut Japan off from any contact with the outside world and had instituted a set of controls that provided the nation with a strong central government. The peace and stability led to a rapid expansion of Japan’s economy, rapid urbanization, and real increases in the fortunes of many Japanese. Yet despite these many gains, there were frequent peasant protests and popular uprisings, the frequency increasing with time.

One Japanese scholar, Aoki Koji, has determined that there were a total of 7,664 incidents of social violence and political protest between 1590 and 1877. Another scholar, James White, when examining Aoki’s research, found peasant, manorial, and other protests more frequent

> SAKURA SOGORO

Sakura Sogoro (also known as Sakura Sogo) was a farmer and a folk hero of the early Edo period (1600–1868). His real name was Kiuchi Sogoro. Sogoro was the headman of a small farming village in the Sakura domain in Shimosa Province (now a part of Chiba Prefecture near Tokyo). According to legend, in the 1640s or 1650s the governor (daimyo) of the province caused considerable suffering among the peasants by levying very heavy taxes and imposing harsh forced labor; Sogoro petitioned the governor for a reduction in taxes. When the governor refused to act on his plea, Sogoro went alone to Edo (now Tokyo) to submit an appeal directly on behalf of the peasants to the shogun himself. By directly appealing to the shogun, Sogoro was risking his life, as this was an act punishable by death. However, the shogun accepted Sogoro's formal plea and ordered a complete investigation of the taxation and labor practices in the Sakura domain. Despite his success, however, Sogoro and his entire family were executed for his actions by local authorities, who resented Sogoro's audacity in going over their heads directly to the shogun.

Sogoro's defiant action has become a part of the legendary history of peasant protest in Japan, and it is difficult for historians to separate fact from fiction. A 1652 village register lists a farmer named Sogo, and an early-eighteenth-century gazetteer lists the execution of a certain Sogoro, but it is difficult to determine the accuracy of the many stories and kabuki plays subsequently written about Sogoro.

—Daniel A. Métraux

and contentious in Europe than in Japan for the same period. The three peak periods of popular uprisings (*ikki* or *hyakusho ikki*) were the 1780s, 1830s and 1860s, corresponding roughly with periods of famine and political change.

Most Tokugawa uprisings were nonviolent. Peasants would leave their land to avoid paying taxes or would petition authorities directly or indirectly against high land taxes, forced labor, and other burdens placed on them by ranking officials. The uprisings lacked any revolutionary zeal; there were no demands for enhanced rights or for changes in the way that Japan was governed,

but there were concerns about fairness, reciprocity, and the compassion of authorities.

Many protests came as a result of efforts by authorities to extract more than they were getting from those they governed. Land taxes remained stable and relatively fair throughout the Tokugawa period, but the peasant also faced a vast array of other taxes and fees that could become a major drain on his income. Disputes could develop from unfairness exhibited by village officials or could represent a communal protest against excessive demands for additional taxes or *corvée* labor.

During the first half of the Tokugawa period many protests were initiated by influential villagers, such as the village head who acted as the liaison between villagers and samurai officials. The Tokugawa village was generally autonomous. Higher authorities generally let local officials rule undisturbed as long as the villagers paid taxes, kept protest to a minimum, and followed the law, but when protests occurred, the first concern of authorities was to get the farmers back to work. Authorities often received petitions or heard grievances, promised to study the matter, and quite often made changes to satisfy the protesters. But authorities also often sought out those who had started the protests and punished them harshly.

Peasant protests after 1750 were generally more violent, larger in scale, and more defiant against authority. Uprisings involving thousands of peasants from several adjoining jurisdictions were common. The protests tended to be well organized and planned and were thus more effective in resisting the authorities. Unlike the past, when protests were frequently led by village headmen and other local officials, the post-1750 uprisings often were organized by the peasants themselves. A 1771 peasant revolt in Tamba province (now a part of Kyoto and Hyogo prefectures) broke out when the provincial government attempted to establish a monopoly over the distribution of cash crops in the markets of this agriculturally rich region. More than 5,000 peasants attacked many government offices and destroyed several establishments of rich merchants. It took several months and military forces from other regions to put down the rebellion.

Some protests after 1830 had a more political nature. Peasants on several occasions started the uprising to achieve political reform within their village organizations. An ikki in Choshu domain (now Yamaguchi prefecture) centered on a strong effort to remove the current village headman and more democratic procedures for selecting future leaders. There were numerous campaigns for the dismissal of allegedly corrupt or unscrupulous village officials, including times when protesters openly burned land registers and other tax-related documents. Worried by the changing nature of these protests, the shogunate and domainal governments adopted stronger measures including firm military force in their suppression.

Occasional uprisings continued through the early part of the Meiji period (1868–1912) when the new government employed heavy land taxes to fund its expensive modernization and Westernization campaigns.

Mardijker—Creoles in Batavia

At the beginning of the seventeenth century, the Dutch took prisoners of war in what had previously been the Portuguese-occupied territories of Malacca, India, and Ceylon and brought many of them to Batavia. These prisoners included many people who, in the course of Portuguese Christianization, had adopted the Portuguese names of their respective masters and had been released from slavery, which in turn led to their later designation as “Mardijker,” a Dutch corruption of the Sanskrit term “Maharddhika” (meaning a respectable and influential person), which acquired the meaning of a freed slave and his descendants in the Malay archipelago.

In Batavia, many of those who had been captured were initially reenslaved but were freed as soon as they became members of the Dutch Reformed Church. Since the practice of

Catholicism was prohibited, believers converted in large numbers, but those conversions tended to have a merely formal character. Catholic and syncretic rituals continued to be practiced. The Mardijker spoke a creolized Portuguese that up until the second half of the eighteenth century served as the lingua franca among those who were neither colonialists nor slaves but who lived as free citizens (*vrijburghers*) in Batavia and its environments, the so-called Ommelanden.

The Mardijker have never been a distinct ethnic group but instead are a category of people that included different free populations of southern and Southeast Asian origins who did not maintain an exclusive identity of origin. Among them existed several subcategories as well as overlappings with other groups of people. During the seventeenth and eighteenth centuries the Mardijker formed one of the largest populations among the free inhabitants of Batavia and were also referred to as “Black Portuguese,” “Black” designating them as Asian and “Portuguese” referring to their (colonial) background and to the language they spoke.

The Mardijker worked as soldiers, merchants, watchmen, and poultry and vegetable retailers. Many of them became part of the emerging Eurasian or Mestizo social stratum, consisting mainly of the descendants of European men and Indonesian women. This category of people was socially and culturally positioned between Europeans and natives but never became established as a separate group in Indonesia. The daughters from such Eurasian families often married Europeans and thus perpetuated the European line, whereas boys were often trained as soldiers and usually married Christian natives or women belonging to the Eurasian and Mardijker categories. Children born out of wedlock between Indonesian women and European men were often included in the Mardijker category. Some Mardijker became renowned and wealthy and, on account of their closeness to the colonial rulers, worked in influential positions for the Vereenigde Oostindische Compagnie (VOC, or Dutch East India Company). They established themselves as merchants and thus enjoyed a comparatively high social status within colonial society.

Another group among the Mardijker were the Papanger, a group whose name derives from

THE BETAWI

The Betawi (Malay for “Batavia”) came into being through the processes of creolization during the time of Dutch colonialism. From the seventeenth century onward a small proportion of their ancestors had been exiled to Batavia from different southern and Southeast Asian regions, areas that had been conquered by the Dutch from the Portuguese. Others were brought to Batavia from Bali and other islands of the Indonesian peninsula to serve as slaves and soldiers for the Dutch colonizers and as servants for other influential foreign populations like the Chinese. Due to the fact that the Dutch expelled the indigenous Javanese population from Batavia for fear of rebellions during this period, it was the Betawi who came to be considered the *orang asli* (natives) of Jakarta. In time, many people who used to identify themselves as Sundanese, Ambonese, Chinese, Mardijker, etc., came to identify themselves as Betawi. As slaves and servants, the Betawi had had little access to modern education during colonial times and stuck to their traditions and their Muslim faith more than those in closer contact with the colonial elite and their educational system. Consequently, the Betawi—with few exceptions—were not among the Indonesian elite after independence was achieved in 1949. Today around 2.5 million people in Jakarta consider themselves Betawi, together with another 2.5 million in the neighboring communities. In the 1960s and 1970s the Betawi were (re-)discovered by the state and the public as symbolizing both traditional and indigenous identity while at the same time transcending ethnic boundaries.

—Jacqueline Knörr

Papango, a region (and ethnic group) on Luzon, or the Philippines, from where they were brought to Batavia in the middle of the seventeenth century. They were accorded the status of free citizens after spending many years serving as soldiers for the VOC.

In 1661 23 Mardijker families originating from Bengal and Coromandel were settled in Tugu, an area in northeastern Jakarta. They differentiated themselves from the natives in many ways: through their Christian religion but also through their language, clothing (wearing black

clothes and Portuguese hats until the end of the nineteenth century), and socioeconomic status. They often owned rice fields in which members of the indigenous population worked. As a result the Tugu were considered collaborators of the Dutch, and during World War II many of them were murdered or put in labor camps during the Japanese occupation (1942–1945). When independence was achieved in 1949 many Tugu fled to the Netherlands, where their descendants still refer to themselves as Tugu today.

However, as increasing numbers of slaves arrived from eastern Indonesia and other parts of the Indonesian archipelago, most Mardijker—like most other non-European inhabitants of Batavia—became part of a process of creolization that took place from the middle of the seventeenth century onward and in the course of which the Betawi emerged. Toward the end of the eighteenth century only a few descendants of the original Mardijker remained. Apart from those who had become Betawi, some continued to belong to the Eurasian sphere of Batavian society and, for the most part, left Indonesia for the Netherlands after independence had been achieved. A few subgroups of the Mardijker—all of them Christians like the Tugu—continue to live in Jakarta in small numbers.

Crossing Over— Cultural Transformation in Portuguese India

Although a fair number of European travelers, missionaries, and explorers had been to eastern and southern Asia previously, especially from the mid-thirteenth century onward, direct and regular contact between Europeans and the peoples of the so-called Indies really began when the Portuguese sailed into the Indian Ocean and reached southern India in May 1498. It could be argued that the network of fortresses and trading posts of the Portuguese seaborne empire also functioned as cultural intermediaries. The Portuguese were cultural brokers, introducing Western values and customs to the East. Beginning as an expedition in search of oriental spices and establishing trading contacts, the Portuguese made a lasting impression on the Asian societies with which they came into contact. The Portuguese employed a variety of methods to entrench themselves in the Asian trade, exploiting regional conflicts and mistrust within ruling families and entering into marriages with Asian elites and partnerships with local traders.

In India, cross-cultural contact widened the horizons of both the Portuguese and the Indians, where the Portuguese presence was spread out in various locations such as Daman, Diu, Bassein, Chaul, Bombay, Korlai, Delhi, Bijapur, Golconda, Madurai, Goa, Cochin, Mangalore, Negapatnam, São Tomé, Chittagong, Calcutta, Nagar Haveli, and Dodra.

The Portuguese presence throughout southern and eastern Asia was characterized by two major concerns, trade and proselytizing, and in India they sought “Christians and Spices.” Those Indians who became “Lusitanised” by converting to Roman Catholicism and speaking Portuguese became identified with the Portuguese.

The Portuguese impact in India is immediately visible in architecture, both religious and secular. Goa’s position as “the Rome of the Orient” and 450 years of Portuguese control of part of Goa have left buildings that are a testimony to cross-cultural exchange. In Sri Lanka (Ceylon) as well as in India, a new style of furniture, Indo-Portuguese, resulted, incorporating local wood with European designs and motifs. The Portuguese also introduced Western Renaissance art to Asia, as seen in a number of Mughal paintings. Western motifs and designs were also introduced to Asian jewelry.

European clothing, which involved tailoring to Western styles, was introduced, and men began to wear trousers and shirts, while women wore skirts and dresses. The Portuguese also introduced European types of liquor and Portuguese food, such as bread and cakes.

The first writings based on European models—biographies, histories, and grammars—emerged from Goa. Although the Portuguese had extended their network to other regions in Asia—Sri Lanka, Malaysia, Indonesia, China, and Japan—evidence suggests that the Goans were the first Easterners to write in Western languages (Portuguese, Latin, French, and English). By learning Portuguese and other European languages, Asians also had access to Western literature.

Though Portuguese rule was short-lived in many parts of India, such as Kerala and Bengal, cultural transformation left its imprints on the

Se Cathedral Church in Goa, commissioned by the Portuguese viceroy Redondo and consecrated in 1640. (Mikhail Nekrasov)

▶ INDO-PORTUGUESE

One of the most important outcomes of cross-cultural contact between the Portuguese and South Asians was the evolution of Portuguese-Creole languages. Although interpreters were engaged in the initial phase of the Portuguese presence in the Indian Ocean and beyond, the nature and extent of contact necessitated a direct means of communication. Portuguese-based creoles were spoken in the areas of the Portuguese official and unofficial empire, bridging the communication gap between Westerners and Easterners. Generations of *mestiços* and *mestiças* born out of unions between the Portuguese and Asians enhanced the longevity of these languages.

Portuguese-based contact languages were not limited to the periods of Portuguese dominance in

portions of Asia. In Sri Lanka (Ceylon), the local Indo-Portuguese (nowadays called Sri Lankan Portuguese Creole) was spoken during the Dutch (1656–1796) and British eras (1796–1948) and has survived to date among the Portuguese descendants in the Eastern Province (Batticaloa and Trincomalee) and among the African descendants in the Northwestern Province (Puttalama).

Indo-Portuguese was a valuable tool for those Portuguese who moved from one enclave to another. Being related to other Asian Portuguese Creoles, such as Malacca Creole Portuguese (Papia Kristang) and Macau Portuguese Creole, Indo-Portuguese speakers had a linguistic advantage when moving within those regions of South and East Asia touched by the Estado da Índia.

—Shihan de Silva Jayasuriya

local Indian languages. A new language, Indo-Portuguese, became a language of discourse among peoples of various cultures. Dialects of Indo-Portuguese were spoken in Negapatnam, Mangalore, Cochin, Korlai, Bassein, Bombay, Daman, Diu, and Sri Lanka. Those who were bilingual or multilingual in Portuguese and in the local languages facilitated the transmission of Portuguese words into such languages as Konkani, Bengali, Gujarati, Malayālam, Sinhala, and Malay. Konkani, the language of Goa, borrowed such basic Portuguese words as *advogado* (*advogād*, meaning “advocate”), *Agosto* (*āgôsto*, “August”), *Amêndoa* (*āmend*, “almond”), *prancha* (*parānc*, “dagger”), and *semana* (*sumān*, “week”). Gujarati, spoken in Daman and Diu, also borrowed Portuguese words such as *compasso* (*kampās*, “compass”), *mármore* (*mar-mar*, “marble”), *prancha* (*parāncb*, “plank/board”), *sapato* (*sapát*, “shoe”), and *toalha* (*tu-val*, “towel”).

European music was also introduced to the East by the Portuguese. Through the Catholic Church, the Portuguese introduced a Western style of music and song that included new concepts such as harmony. Not only did the Goans learn Western choral music, they mastered it to such a high standard that in 1663 when they sang an oratorio of the Baroque master Giacomo

Carissimi in Bom Jesus at Velha Goa, the pope’s legate, who was at the performance, noted that he felt that he was in Rome. Goan folk songs were also affected due to Portuguese contact. In Sri Lanka, Chorus Baila has evolved from musical forms brought by the Portuguese and has become the most popular form of song.

The distance and resources involved in sailing to the Indies meant that many Portuguese did not return to their country. This inevitably led to a Portuguese diaspora.

As very few Portuguese women went on the voyages to India, at least in the initial stages, inevitably marriage and concubinage with local women resulted. Indeed, intermarriage was officially encouraged by Portuguese viceroys such as Affonso Albuquerque. Married Portuguese soldiers (*casados*) were allowed to settle down, whereas unmarried soldiers (*soldados*) were transferred from one fortress to another. Moreover, many Portuguese who left the official empire, or Estado da Índia, entered into unofficial trading networks and settled down in southern and eastern Asia.

Serfdom in Eastern Europe and Russia

In the 1980s at a conference on the causes of economic backwardness in eastern Europe, prominent British historian Eric Hobsbawm asked a seemingly simple question: Why was Albania not as rich as Switzerland? Backwaters for much of their histories, both countries were after all mountainous, thinly populated but fiercely independent, and poor in resources except for mercenary soldiers whom they supplied for generations. Yet this seemingly incongruous question of comparing the societies that became Europe's richest and poorest points to one of the most complex historical dynamics that shaped the entire continent. Albania and Switzerland developed in completely different contexts, and serfdom played a crucial role.

Serfdom refers to the condition of a peasant who does not enjoy the rights of a free person but is not a slave. The history of serfdom in Europe is not a monolithic one. The institution developed throughout the continent as a relationship of dependence; peasants depended on the protection of their manorial lord in exchange for working the land and paying rent. However, this practice has been likened to slavery, as the peasants did not have freedom of movement. They could not leave the estate without the permission of their lord, and the lord had the right to demand labor, money, or goods from the serf, who did not have any recourse for negotiating the terms.

Between the fifteenth and eighteenth centuries, western and eastern Europe embarked on contrasting paths of socioeconomical development. Serfdom waned in western Europe, which became a center of the capitalist world system of trade; this economic system shifted the world's major trade routes away from the Mediterranean and the Baltic toward Europe's

Atlantic seaboard. At the same time, eastern Europe experienced the erosion of peasant rights and landholdings and the extension of manorial cultivation and the intensification of serfdom; by the eighteenth century the region was relegated to the role of a periphery that exported natural resources or produced semiprocessed primary commodities for its western counterpart. Some scholars argue that such economic regression played a decisive role in the strengthening of serfdom in eastern Europe. For example, lower grain prices compelled owners to produce more grain to maintain their former revenues by demanding more dues and services from peasants. These scholars point to Russia during the fourteenth and fifteenth centuries and to Hungary and eastern Germany in the seventeenth century as prime examples of this process. Other historians, citing Russia's experiences in the sixteenth and seventeenth centuries, eastern Germany after the Thirty Years' War, and eastern Prussia after the plague epidemic in the early eighteenth century, highlight the role of wars and epidemics that caused serious depopulation and labor shortages, which obliged the landowners to increase their demands for the surviving peasants.

Once entrapped by serfdom, the peasants became little better than the slaves of their landlords. They were not allowed freedom of movement; any serf who left his or her landlord's estate without permission could be retrieved and punished. While the serfs were allowed to administer their villages on their own terms, they remained obligated to pay dues and serve the lord. They were compelled to render services (plowing, sowing, harvesting, haymaking, etc.) to the lord on three or five days and sometimes even six days a week. In the Danish province of Holstein (which was primarily populated by German-speaking people), some serfs were required to produce crops such as grain and wool in addition to taking their masters' ships to sea in order to catch fish to be sold at market. In eastern Germany, the practice of *Gesindezwangsdienst*, first mentioned in 1534, required all serf children to work as domestic servants in the house of the lord for up to four years.

Several factors contributed to the development of serfdom in the east. Eastern Europe is largely landlocked and lacks the navigable rivers

► BURDEN OF SERFDOM

Exploring the experiences of the serfs posed a considerable challenge because the overwhelming majority of them were illiterate and could not produce written records about their lives. But indirect evidence about their conditions can be found in the writings of travelers, who, although belonging to the elites, oftentimes recorded the wretched conditions of the rural masses. One such writer was Alexander Radishchev (1749–1802), whose criticism of Russian political and social conditions resulted in his exile to Siberia. The following excerpt is Radishchev's description of his meeting with a serf, whose heavy burden of labor would have been common to other serfs:

The corduroy road tortured my body; I climbed out of the carriage and (walked). A few steps from the road I saw a peasant ploughing a field. The weather was hot. . . . It was now Sunday. . . . The peasant was ploughing very carefully. The field, of course, was not part of his master's land. He turned the plow with astonishing ease.

"God help you," I said, walking up to the ploughman. . . .

"Thank you sir," the ploughman said to me, shaking the earth off the ploughshare. . . .

"You must be a Dissenter, since you plough on a Sunday."

"No, sir, I make the true sign of the cross," he said, showing me the three fingers together. "And God is merciful and does not bid us starve to death, so long as we have strength and a family."

"Have you no time to work during the week, then, and can you not have any rest on Sundays, in the hottest part of the day, at that?"

"In a week, sir, there are six days, and we go six times a week to work on the master's fields; in the evening, if the weather is good, we haul to the master's house the hay that is left in the woods. . . . God grant that it rains this evening. If you have peasants of your own, sir, they are praying to God for the same thing."

". . . But how do you manage to get food enough, if you have only the holidays free?"

"Not only the holidays: the nights are ours, too. If a fellow isn't lazy, he won't starve to death."

and coastal waters that made it easier for west European centers of trade and manufacturing to interlink. In the Balkans, Ottoman monopolistic policies, often designed to provision Constantinople at artificially low prices, played an important role in smothering the development of bulk trade. Well into the eighteenth century eastern Europe suffered from low population densities and a comparative scarcity of large towns, which further limited commercial opportunities. Most of the existing towns in eastern Europe were small, and they never developed a real urban middle class. In Hungary and Poland, for example, this meant increasing stagnation in economic life and the decline of the towns to the level of rural communities.

In the sixteenth to seventeenth centuries, eastern Central Europe also suffered from profound socioeconomic crises manifested in natural disasters, famines, urban and rural unrest,

and recurrent warfare (e.g., Ottoman invasions, the Thirty Years' War, and the Polish-Swedish wars). The religious warfare of the seventeenth century led to the persecution and emigration of Protestants, Jews, and freethinkers, who played an important role in economic activities. These crises also contributed to the development of reactionary alliances between monarchs and big landowners, who made concerted efforts to restrict the rights and mobility of the peasantry to extract increased dues and labor obligations. Thus, in Moravia and Bohemia the Thirty Years' War stunted the growth of the local cities and ensured the political supremacy of the nobility over the towns. As argued by the eminent Czech historian Josef Polisensky, these developments were "incalculably deleterious, setting back the development of communities by nearly a century and burdening them with a shortsighted, incompetent upstart nobility which could only

prosper at the expense of the peasantry.” Thus, the economies in central and eastern Europe remained largely traditional, allowing the landlords to consolidate their powers over greater tracts of land and in the process subjugating peasants to serfdom, in many cases for the first time. As the noble estate owners became more powerful and increased their demands for dues in cash, kind, and labor, the peasantry was increasingly subjugated. But serfdom was not uniformly enforced throughout eastern Europe, and allowance must be made for varying political circumstances. Serfdom in Bohemia or Hungary was not the same as in Austria, Poland, or Russia. For example, serfdom did not determine political outcomes. Prussia to the west and Russia in the east used serfdom to increase revenue extraction, which then served as the base for the construction of absolutist monarchies. By contrast, Polish aristocratic magnates dispensed with a strong monarchy. While a full-blown “second serfdom” emerged in east-central Europe and in Russia, some Ottoman-dominated territories (e.g., Wallachia, Moldavia, Bulgaria) saw the development of the *çiftlik* system that was composed of estates and property that were not directly farmed by the owners but instead served as a source of rents and dues from various types of tenants and sharecroppers. Although repressive, the *çiftlik* system never developed into serfdom because of the continuing high level of peasant mobility (i.e., fleeing from estate to neighboring territories), which made it difficult to enforce the serf laws binding peasants to the land. Between 1741 and 1746, for example, Wallachia saw half of its peasant families emigrate, while the Romanian peasantry did not experience full juridical enserfment until the late eighteenth century.

Russia, which maintained serfdom until the 1860s, presents the most well-known case of serfdom. In his classic *Lord and Peasant in Russia*, Jerome Blum observed that there could be three categories of serfs. In the first category, a serf was bound to the land and could not be moved by any lord since the serf was first and foremost attached to the land, not a person. The second category included serfs who were bound to the person of a lord and whose condition closely resembled a slave. The lord was essentially the owner of the serf and could move him

or her anywhere and even sell the serf to a third party. In the third and most complex group, a serf was not directly subject to the state but was subject to a lord who in turn was subject to the state. Russia did not experience a formal serfdom until the fifteenth century, when the civil war of 1425–1453 devastated much of Russia. Some Russian monasteries forbade their peasant debtors to move at any time except around St. George’s Day, the day in the pagan calendar when the harvest was completed and thus debts could be collected. By the end of the fifteenth century the Russian authorities, rationalizing that not paying a debt was a crime and forbidding peasant debtors from moving as a crime-prevention measure, extended the St. George’s Day limitation to all peasants, thus binding them to the land. Lords, however, had no authority over the peasants and were limited to collecting rent.

The turning point in the development of Russian serfdom occurred during the reign of Tsar Ivan IV, whose Oprichnina policy (1565–1572) changed the status of Russian peasantry. The tsar granted his loyal Oprichniks personal control over the peasants living on the lands they possessed, allowing them “to collect as much rent in one year as formerly they had collected in ten” and ordering peasants “to obey their lords in everything.” The continued persecutions and Oprichniks’ demand for ever-increasing rents and taxes led to the depopulation of much of the Muscovy, with peasants fleeing on St. George’s Day. Russian landholders, finding their estates being depopulated, then petitioned the tsar to altogether abolish the right of peasants to move on St. George’s Day. The tsar initially partially satisfied their demands by proclaiming certain years as “forbidden years” when peasants could not move but also setting a five-year statute of limitations on the recovery of fugitive serfs.

The Time of Troubles (1598–1613), when the Muscovite Rus plunged into political turmoil, temporarily halted the enserfment process. Thousands of peasants fled from chaos and destruction, leaving entire communities depopulated. The new Romanov dynasty, which came to power at the end of this civil strife in 1613, supported the nobility’s demands for the repeal of the limitations on the recovery of fugitive peasants. In 1649 the new Law Code (*Ulozhenie*)

marked the official establishment of serfdom in Russia and confirmed a legal social-economic framework for Russian society as a whole that reinforced stratification, preserved privileges for the few, and prescribed harsh servitude for the many. Noble landowners benefited from the following measures against the peasantry: all peasants belonging to the nobility listed in census books were placed into legal bondage; the previously existing time limits on search and recovery of escaped serfs, which had been repeatedly extended during earlier decades, were abolished; freedom of movement for serf family members was terminated; harboring runaway serfs was prohibited; peasants were deprived of personal property; and the power of the nobles over their serfs was strengthened.

Race and Class in Colonial Latin America

The ethnic and cultural foundations of Latin America draw upon a mixed heritage of European, African, and indigenous elements. In this regard, the region's history is part of a much larger story about race and class in the early Americas. Unlike English pilgrims in North America, Iberian conquistadors were heirs to a military tradition and came to the New World seeking power and wealth. Leaving behind wives

and children in Europe, early settlers freely mixed with indigenous and, later, African peoples. In the process, new ethnic types were born. In the case of colonial Mexico, the story of Don Martín Cortés is illustrative. The son of Hernán Cortés and his indigenous interpreter and concubine, Doña Marina, young Martín would travel at the age of five to Spain, where he would be awarded a prestigious knighthood and become a page to a future king. Although the young man would never inherit his father's title or estate (because of his illegitimacy), today he is viewed as the forebear of a new Mexican race: the mestizo. Similarly, in Brazil early *mamelucos*—the children of Portuguese fathers and Tupinambá mothers—became cultural intermediaries and are now romanticized as the forerunners of a new hybrid cultural type: the first Brazilians.

In Spanish America, the intermixing of European, Indian, and African peoples led to a myriad of racially mixed groups that were collectively known as *castas*. The individual terms that defined different ethnicities within the *casta* system varied by region. Generally speaking, the child of a Spaniard and an Indian was called a mestizo, from a mestizo and Spaniard came a *castizo*, from a Spaniard and African came a *mulato*, from an Indian and African came a *zambo*, and so forth. The *casta* system was discriminatory in both theory and practice, with European-born whites at the top of the racial hierarchy and Indians and Africans at the bottom. In the middle of the hierarchy, mestizos and other in-between groups frequently sought to “whiten” themselves and their children. In this regard, the child of a castizo and a Spaniard was legally considered a Spaniard. In the case of unions between Spaniards and Africans the principle was the same, but African blood was considered darker than its indigenous counterpart and was thought to be distinguishable through the third and fourth generations. In addition to the general categories above, a host of designations were employed to describe additional *casta* variations, including *moriscos*, *albinos*, *cambujos*, *albarazados*, *barcinós*, *chamisos*, and so forth. By the middle of the eighteenth century, Spanish preoccupation with race would go so far as to become an art in the form of *casta* paintings: multipanel works that depicted the ethnic characteristics of 16

SPAIN AND PORTUGAL IN THE AMERICAS, 1750

> JOSÉ DA SILVA TERRA

The story of José da Silva Terra, a merchant and miner in late-eighteenth-century Brazil, illustrates how notions of race and ethnicity underpinned legal discrimination in the Iberian world. A middle-aged military captain living on the edge of Portuguese America in the captaincy of Mato Grosso, Terra was a respected member of local society and was responsible for a large household, including a *mulata* wife, various children, and numerous elderly slaves who were too old to work. Additionally, he owned more than 80 slaves who were actively employed in the region's gold mines. Writing to the Portuguese Crown in 1792, the faraway merchant asked that one of his sons be granted an office in the local colonial bureaucracy. Significantly, his high standing in the distant town would hold little sway in the Portuguese court. Shortly after his son personally made the 12-month journey to Lisbon to deliver the petition, Queen Maria I declined the request. Her decision was based on a written recommendation from one of the region's former governors and reflected the man's personal knowledge of the son's ethnicity: "I

know the supplicant [the son] perfectly well and do not consider that he has the necessary capacity for this office, principally being as he is the son of a *mulata* . . . and by consequence, belonging to that class which in Brazil are called men of color. And under no condition whatsoever is there any way in which he could serve, . . . for even supposing that he is married as he himself claims, there are still many white men in that remote colony who also have children and who are equally poor and in need."

different racially mixed groups. Although surviving paintings often portray idyllic and exotic scenes, they were not intended to reflect a peaceful coexistence between different ethnicities but rather to reinforce the existing racial hierarchy and the notion that each ethnic group had a specific place in an orderly society.

In the case of Brazil and the Caribbean, African slaves and their descendants were much more prominent than elsewhere in the Americas. By implication, Africa would play a much more important role in the ethnic and cultural makeup of these regions. As was the case in Spanish America, the Portuguese and French employed a series of race-related terms to describe how blacks and their multiethnic descendants fit into society. Additionally, they also employed particular terms to describe cultural differences among different slave groups. In the case of Brazil, for example, a recently arrived uneducated and unchristian slave was called a *boçal*. A *ladino*, on the other hand, was an acculturated Christian slave born in Africa, and a *crioulo* was a

Brazilian-born slave. Similar to mestizos in Spanish America, mulatos in Brazil and the Caribbean were considered an in-between group. Accordingly, they enjoyed a measure of social mobility that was denied blacks. Although demographic information is imprecise, scholars estimate that 80 to 90 percent of slaves in Brazil were black as opposed to mulato. Writing in the early eighteenth century, the Jesuit father Antonil reflected on this differing status. Acknowledging the horrors of African slavery and the difficulties of Portuguese settlers, Antonil's comments about mulatos are particularly intriguing: "They are usually luckier than anyone else in Brazil . . . thus verifying the proverb which says that Brazil is a hell for blacks, a purgatory for whites, and a paradise for *mulatos*, both male and female."

Notions of race and ethnicity frequently played a role in legal and economic discrimination. Town councilors in Spanish America, for example, could only be elected to office if they were white male property holders. Similarly, laws in colonial Brazil allowed a husband to kill

both his wife and her lover on suspicion of adultery unless the husband was from a poor racially mixed group and the adulterer was someone of high standing. In Spanish America, forced labor in the form of the *repartimiento* and *mita* was reserved for indigenous society. Similarly, chattel slavery was the domain of Africans and their descendants across the Americas.

Notwithstanding these examples, early Iberian conceptions of race should not be understood as completely fixed. Depending upon circumstances, individuals from racially mixed groups could sometimes create favorable places for themselves in the racial hierarchy. A mestizo in a peripheral region of Spanish America, such as the highlands of Peru, might very well be considered white in local society, effectively enabling him to control property and to serve in municipal offices. Similarly, mulatos who rose through the ranks of Brazilian society did so in spite of the color prejudices against them and in the process frequently came to be considered white. The story of João Fernandes Vieira is illustrative. The mulato son of a female slave, Vieira was born on the island of Madeira in 1613. In later years he would migrate to Pernambuco, where he would accumulate significant capital. The owner of at least five sugar plantations, this well-to-do mulato would subsequently play a decisive role in driving the Dutch from northeastern Brazil. Thereafter, contemporaries glossed over his humble beginnings. Later authors would even go so far as to claim that Vieira was the legitimate son of an important Portuguese nobleman. If these circumstances did not exist, individuals of mixed blood could also obtain something from the Crown called a "Certificate of Whiteness." Purchase of such a document guaranteed that the owner would be treated as a person of Spanish or Portuguese descent regardless of heritage. This was especially useful for noblemen who did not have any European children to leave their titles to or for those sons of rich men who aspired to enter the Church or university or receive privileges from the Crown. By implication, race in colonial Latin America can best be understood as a social rather than biological designation, interweaving notions of ethnicity with early modern conceptions of power, wealth, gender, and class.

African Communities in Belize

Located in Central America and nestled between Mexico, Guatemala, and the Caribbean Sea, Belize is home to two Afro-Caribbean cultures, the Creoles and the Garinagu. The Creole and the Garinagu are descendants of African people who were introduced to this region by slavers and colonizers beginning in the fifteenth century. Both groups share an African heritage, but their experiences with slavery and resistance against slavery and colonization have shaped their culture, religion, and language in distinct ways.

In Belize, the term "Creole" denotes an ethnic group whose members share an African and European ancestry but who may be mixed with any number of other racial and ethnic backgrounds. Creole, the ethnic group, is distinguished from Kriol, a language that most Belizeans, regardless of ethnicity, speak. The designation Creole was used in the early 1700s after the British baymen brought African slaves via Jamaica to British Honduras, the former name of Belize, to cut logwood, which was used as a dye in Europe, and mahogany, valued in England for furniture construction.

From the inception of British settlement of Belize, the population of Creoles was greater than that of whites. This continued even after the abolition of slavery in 1838 and the conversion of British Honduras into a formal colony in 1871, but the British cultivated a relationship between themselves and the Creoles through

work, education, religion, and language. Therefore, the British maintained social, political and economic dominance. The Creoles' majority status, as well as the Creole elite's associations with the British, led to their dominance in civil service and politics. However, for the vast majority of Belizeans, British slavery and colonization used law to censor and disband African languages and traditions—such as songs, dance, drumming, waking the gone—and used education to teach that England, the Anglican Church, and English traditions were the epitome of civilization. The history and sociology of the formation of Creole identity away from Africa toward Britain encouraged ethnic tensions that worked to keep the Creoles and the Garinagu peoples, two black cultures, apart.

The Garinagu throughout Central America and Belize are descendants of shipwrecked and runaway African slaves and Arawak and Carib Indians who lived on the island of Saint Vincent. Referred to as Garifuna in Belize, the term “Garinagu” signifies the nation of people who speak Garifuna. Persecuted by the British, French, and Spanish, the Carib Indians and escaped African slaves joined forces—through marriage and through militaristic arts—to fight the British and enslavement in the 1600s and 1700s. Resistance against the British continued into the late 1700s, when the British exiled the Garinagu to the island of Roatan off the coast of Honduras.

In the early 1800s, Garifuna people migrated to the southeastern shores of British Honduras. Here, they began to settle in increasing numbers, despite British Honduran settlers' attempts to hinder and then limit their migration for fear

they would incite slave rebellion. While the British settlers eventually allowed the Garinagu to settle permanently because they provided the settlement with workers for the logging camps and with needed agricultural products, they were successful in keeping the Creoles and Garinagu apart by labeling the latter as cannibals and dangerous. Attempts were even made through legal means to fine parties that associated with any Garifuna. Isolated from the main settlement in Belize City, Garinagu culture and the Garifuna language flourished. Ethnic tensions between the Creoles and Garinagu, created by the British during slavery, continued in Belizean society and worked to prevent intermarriage and to encourage discrimination.

■ Introduction: Gender and Social Hierarchies

Gender roles in any society usually consist of idealized behaviors to which the members of each sex are expected to adhere or, conversely, expected to avoid. While variations in the early modern period existed across ethnic and regional boundaries, certain similarities existed. Women across the globe

were expected to care for their homes and families. This did not necessarily mean that they were to be isolated at home. Some had a high degree of freedom, as was the case with Mohawk women in North America. Although the women of the Mohawk tribe were the ones to care for the children and provide domestic du-

ties, they also seemed to share an almost equal rank with men in the governance of the tribe. In fact, their role in providing food for the tribe brought with it status as the owners of Mohawk lands. In societies where it was the ideal for women to remain socially isolated, typically gender role norms were applied more strictly to the highest strata of society. While women of all classes were expected to strive to achieve these ideals, the reality of life for those women on the lowest rungs of society prevented them from being able to meet such standards. A woman of elite status could more easily remain isolated from the outside world because it was not necessary for her to work outside of the home. An elite woman's movements were strictly monitored, and any misstep could lead to social disaster for the family. No matter how harsh the social restrictions, women usually managed to find ways to assert power, even if it was only in their own households. Elite women in China lived an existence of extreme restriction, exhibited in both their gender roles and bound feet, but they were still powerful as mothers-in-law and first wives.

Even though female gender roles have typically been examined most often by historians, males also have a prescribed gender role in any given society. To add to the complexity of the issue, masculine gender roles are harder to pinpoint than female roles. Again, there are similarities in these gender roles that can be seen across cultures. Male ideals encompassed the counterpart to the feminine roles: the protector of the family and a warrior. Interestingly, the early modern period in both China and Europe saw a new facet added to the masculine ideal: that of a rational, intelligent being. There was also a wide variance in the acceptance of homosexuality in the world, particularly among males. The practice exists in all areas of the world, but was criminalized primarily in Europe, particularly after the Reformation as Protestants and Catholics exerted themselves to prove their piety. This attitude was unmatched anywhere else in the world, and places like Japan not only accepted homosexuality, but transgenderism had an institutionalized place in the Kabuki and Noh theater traditions.

—*Monique Vallance*

Women in China

The period under consideration, 1450–1770, includes the last years of the relatively lax Ming dynasty (1368–1644) and the early years of the more moralistic Qing dynasty (1644–1911). Chinese women, like most women of the age, were largely confined to the private sphere, the realm of home and hearth. Most Chinese women occupied roles that were dependent on their relationship to males: they were mothers, wives, concubines, and servants. A few others made their way through life as courtesans. Both dynasties officially supported a strict Confucian ideology, supporting the notion that keeping the world in balance requires women to focus on family and the “inner court,” the immediate household, insisting that strict separation of the genders is necessary to maintain an orderly society. The Qing were more conservative and tended to take an active role in enforcing their version of family piety more rigorously.

Ideally, the women of the household were organized in a multigenerational pyramid of power. In families with sufficient resources to maintain multigenerational households, mothers-in-law, or the mother of the ranking male in the family, had authority over all other women. Beyond that, wives ranked above concubines and maids, who were sexually accessible to the man to whom they were attached. Concubines and servants in a household incurred the same legal obligation of fidelity as wives. Senior women of a household were responsible for ensuring the good behavior of subordinate women. When children were born to concubines or servants, their father's senior wife was considered their true mother. The death of the ranking male sometimes threw families into disarray; ranking women had full authority over the rest and could protect the status of their own children or take retribution for any past insolence, real or imagined, if they so desired. At times, the subordinate women's birth families or clans could intervene on their behalf, although this brought with it additional expense. In both Ming and Qing times, there were legal restrictions on married women's control of their dowries, particularly their right to take their dowries with them if they were widowed or divorced.

In the Chinese worldview, children are a lifelong responsibility, and the expense of providing a dowry for daughters can be prohibitive. Rural peasant families were less likely to include as many women, but basic organization was similar. Women were part of the economic unit, working in the fields and spinning cloth for sale. There was a shortage of females among poorer families due to female infanticide as well as the migration of daughters into the multifemale upper economic strata as wives, concubines, or servants.

By the mid-fifteenth century the Ming had gone into a long, slow decline, and Ming emperors made few decisions, leaving governance to the bureaucracy. As is often the case, official inattention allowed for (or actually inspired) an effervescence in art and literature. The high rate of literacy, especially among elite women and the more prosperous urban women, gave rise to an explosion in the publishing industry. Women also began taking more prominent roles in the family's economic activities, performing religious rites and participating in public functions. Gentry families internalized the practice of female education, and female literacy remained relatively high after the fall of the Ming.

The notion of the passive victimized Chinese woman has never been the whole story. A society's ideals are rarely a neat reflection of its reality. Shrews, bandits, and prostitutes gained a measure of freedom for themselves, as in truth most women did albeit in a more subtle manner. For centuries the abusive woman, the shrew, has sometimes appeared in cautionary tales and literature. The trend intensified dramatically as the Ming dynasty lost vitality, and the shrew became a frequent cause for lawsuits as well as a stock character in romantic dramas and comic satires. From this distance, it is not really possible to tell whether women were actually "getting out of control" or if these stories grew from the general anxieties of living in a period of dynastic decline.

Whatever the cause of the intensified concern about out-of-control women, the Ming's successors, the Qing, were diligent in their efforts to restore Confucian order. They were a foreign dynasty originating in Manchuria and seem to have tried to offset their foreign origins by demonstrating their dedication to Confucian principles. Qing emperors often involved themselves

in what would normally be private family matters. Illicit sex was a serious matter because it could thwart a male's ability to fulfill his duty to provide sons to continue his own ancestors' line. Female chastity was a matter of intense official concern. By the eighteenth century, the Qing had established stringent standards for female virtue.

The virtuous widow—a woman so chaste that she would remain faithful to her husband even after his death—became an increasingly celebrated figure. The Qing extended the ideal of the virtuous widow to include even young girls who remained faithful to fiancés who died prior to marriage. They made romantic martyrs of those who committed suicide in order to follow a fiancé (sometimes a man whom they had never met) to the grave. There were high honors awarded those who took upon themselves the responsibility of serving a deceased fiancé's parents as a chaste caretaker. It should be noted that marriages were the result of agreement between fathers or those acting in the position. There was no requirement that bride or groom consent.

There were few protections for women. A husband could legally kill a wife guilty of adultery. Both law and custom allowed husbands to beat their wives, but as Matthew Sommer noted in *Sex, Law, and Society in Late Imperial China*, the Qing prohibited "breaking injuries," those involving broken bones or teeth. Nevertheless, Qing courts would be lenient if it appeared that the wife deserved the beating. The Qing Qianlong emperor (r. 1736–1795) excused one man for murdering his wife after she insulted the man's mother, a clear violation of the hierarchy of the hearth.

Qianlong's rule was the apex of Chinese power and wealth as well as the period of the greatest extent to which imperial rulers involved themselves in the private lives of their subjects. During this era, known as the High Qing period, there remained the fond belief that the hierarchy of the home, the eldest male presiding over grateful subjects, would be replicated in the hierarchy of the state, the emperor presiding over grateful subjects. The emperors of the Qing dynasty took their responsibilities seriously and worked arduously to keep the Chinese family in patriarchal balance. By the end of

the dynasty, Chinese intellectuals were speculating that suppressing women was a root cause of Chinese weakness and ineffectiveness, but that was a century and a half in the future.

Concepts of Masculinity in China, 1450–1750

Male and female behavior is largely based on societal conditioning. No one can deny that hormones play an important part in human life, but gender roles evolve under the influence of a complex set of agents, including political expectations, philosophy, ideology, and very real needs for organization and security. Cultures dominated by the European intellectual tradition generally base their perception of proper gender roles on a strict dichotomy, albeit with some blurring around the edges. Whereas the virtues of the stalwart European knight dominated European notions of proper masculinity, Chinese standards were much more complex.

Confucian literature generally presents gender and class distinctions as harmonious aspects of a unified society. The Chinese concept of proper conduct is based on societal role rather than a generic sexual identity. There is a romanticized notion—born from the overly enthusiastic reports from Sinophilic Jesuits—that the dynastic Chinese hierarchy placed peasants in the highest slot, well above merchants and

warriors. It is doubtful if such a hierarchy ever existed outside the minds of hopeful Chinese scholar-philosophers. Dynastic founding fathers generally arrive at the head of an army, even in China. If we put those idealistic notions aside and acknowledge the role of the warrior/soldier figure as well as that of the Confucian bureaucrats, we get a clearer picture of Chinese concepts of masculinity.

The gentlemen scholars of the Confucian classics were depicted as morally superior men, without any evidence of their physical existence, let alone implications of sexuality. The legendary warrior defenders of China, having many of the attributes considered manly in the European tradition, are usually portrayed as chaste, having renounced sexual activity in their pursuit of a moral use of force. The emphasis on restraint serves to underscore the Confucian principle that life runs smoothly when people renounce self-indulgence in favor of strict self-discipline. Still, one could argue that the importance of masculine sexuality in Chinese cultural perceptions was based on two essential considerations: one a positive requirement that men fulfill the specific function of reproduction and the other a negative based on what men were not. It was clearly a male responsibility to ensure that there would be future generations to take over the task of honoring and appeasing his ancestors, thereby keeping heaven and earth in a proper relationship. The other issue was the importance of not being a woman. Women were limited to roles defined by their relationship to men, as mother, wife, daughter, concubine, or maid. Male roles were either gifts from their ancestors (following their father's footsteps) or assumed as an obligation to their family or lineage.

Proper manly attributes for one path might be very inappropriate for another. Many forces, including the tension between Confucian ideology and the need to contain the dangerous forces on the Chinese borderlands, shaped Chinese standards for gender roles. The model of the Confucian gentleman devoted to ethics, philosophy, and art lay at one pole; the noble, selfless warrior lay at the other pole. The balance was never stable for any extended period, but the destabilization arising from the Manchurian Qing conquest of 1644 and the increasing European

THE CHINESE WARRIOR AND THE TEMPTATIONS OF SEX

The notion that women present an unacceptable temptation to warriors may have had roots in earlier dynasties but seems to have reached its romantic apex during the late Ming dynasty. Although there were many novels and dramas during the late Ming and early Qing dynasties, some nearly pornographic in detail, centering on romances between women of varying experience and position and the delicate scholars, the tales of warrior heroes centered on relationships between men, treating women as unwelcome diversions. Of the warrior epics, *The Romance of the Three Kingdoms* was one of the most popular legends, repeated in various novels, poems, and dramas. Two of the central characters are General Guan Yu, later memorialized as the god of war, and Liu Bei, a powerful warlord. In the Ming era two vignettes were added, illustrating the perception of the Ming audiences about the proper relationship between warriors and women. In one of the popular versions of the story, Guan Yu suggests that Liu Bei's sons kill their own wives and children so that there would be no interference with their devotion to Liu Bei. In another version of the tale a beautiful, desirable woman named Diao Chan was presented to Guan Yu after the death of her husband. Rather than accepting her as his just reward, Guan Yu pulled his sword and decapitated her in order to spare himself temptation. It is difficult to reconcile the idea that women presented a greater threat to warriors than to scholars, but it may arise from a tacit recognition that a diverted scholar loses only time and prestige whereas negligent warriors may result in the loss of entire villages. This explanation, however, does much violence to the idea that scholars occupied a very high position in the social hierarchy, with warriors far below them. Of course, the explanation may simply be recognition that a society's ideals may not always represent its reality.

—Carolyn Neel

presence during the early modern era combined to make sanctioned male roles particularly unstable during the period under consideration. Even during the most stable periods, interpretations varied along class boundaries; merchants, craftsmen, soldiers, and lower-level bureaucrats

had visions of the perfect male that were very different from that of the scholarly elite.

The honorable execution of one's legitimate duties was the highest responsibility and was clearly more important than an arbitrary set of gender-based expectations. In *The Fragile Scholar*, Song Geng notes that dichotomies of "mind/body," "masculinity/femininity," or "heterosexual/homosexual" were absent from Chinese literary discourse prior to the traumatic conflicts of the nineteenth and twentieth centuries. The concept of a yin/yang binary did play a role, yet these are flexible properties less directly representative of "female/male" attributes than often thought, having more to do with political and hierarchal considerations than gender. Nothing can exist without a measure of each. The same concept applies to the *wen/wu* balance: *wu* representing the fierce warrior and *wen* the artist/scholar. The *wu* attribute is most frequently associated with Guan Yu, a war god generally depicted with a ferocious red face and bushy beard. Although seemingly testosterone driven, Guan and other *wu*-based characters in popular novels and legends remain celibate, never succumbing to womanly wiles or enticements. The more prototypical *wen* male, the fragile scholar, is traditionally the more seductive or, at least, the more easily tempted. Like yin/yang, however, the Chinese perceive the presence of both *wen* and *wu* characteristics in all males, although rarely in perfect balance.

Gender identity is always fluid but becomes more so during times of stress. In the early Ming dynasty, love poems and romantic fiction portrayed the hero as a sensitive young artist/poet/scholar, physically pale and thin with a slender waist and pale skin and often having sensuous red lips. His delicate sensitivities are of the sort that Europeans would traditionally associate with femininity. If one were to search for a cultural meaning in this, one might well conclude that the highly refined romantic heroes of the early Ming were envisioned as a means of distinguishing the cultured Chinese from the uncouth, violent Mongol Yuan dynasty. As time passed and the nomadic pressures on China's northern borders caused security to be a concern, the men of Chinese romantic literature began to be described as more athletic, with

broad shoulders and muscular arms. The fragile scholar retreated in favor of the protector. The steppe warriors who formed the Qing dynasty (1644–1911) brought with them conceptions of masculinity that were similar to their Mongol predecessors. During this time, when the invading Manchus dominated the military leadership as well as the martial arts, once again the Chinese ideal male reverted to the very refined (and sexual) wen scholar, in direct opposition to the barbarian warrior wu Manchus.

Europeans became infatuated with all things Chinese, but their fascination (sometimes described as Chinese “madness”) reached its apex in 1750, coincidentally near the end of the period under consideration. By 1750, some Europeans were beginning to objectify the Chinese as “effeminate” or “decadent.” Their impact on Chinese concepts of masculinity was a shadow on the horizon. After the traumas of the twentieth century, the ideal of the delicate scholar was marginalized in favor of that of the Europeanized warrior gentleman. However, Chinese history continues to unfold.

Women and Family in Sub-Saharan Africa

African women were central to the process of state building and commercial growth in the era between 1450 and 1750, forging cultural and lineage connections that extended territorial

belonging through family alliances. From the Swahili city-states of the East African coast to the trade entrepôts, kingdoms, and empires of West and Central Africa, women rulers and concubines used sexuality and family to create allegiances. Female associations negotiated the cultural complexity of the era, which saw the expansion of both Islam and Christianity and helped expand sub-Saharan political economies.

From the Iron Age on, African women supported their families through agricultural activities, with a near monopoly over the technology and production of critical crops such as rice in the Senegambia. While restricted from the lucrative production of metals, some women became craft specialists, typically inheriting the knowledge from their mothers, who practiced weaving, pottery making, and basketry with babies on their backs and small children at their sides. In addition to child rearing, women had primary responsibility over cooking activities, which included the gathering of firewood and water. The transfer of women from the households of their fathers to marriage households controlled by husbands was the most important expression of patriarchy experienced in a woman's life.

Intermarriage of European or Arab men and African women served as an avenue for the accumulation of wealth and power for a few individuals. Influential Portuguese African women in the Gambia are described by seventeenth-century European visitors both as transfrontier mediators between cultures and as entrepreneurs in their own right. Since African women often acted on behalf of their husbands in their absence, they were positioned to seize property and broker responsibilities in widowhood. More commonly, however, women themselves were a form of wealth and found themselves subordinated to men's desires and control.

In the Cape Colony of Southern Africa, local Khoikhoi interactions with Dutch settlers produced opportunities for African women to transform their lives. A woman named Krotoa, also known as Eva, appears in the early-seventeenth-century Dutch records of the settlement. Krotoa was a remarkable participant in the multilingual and interactive environment, serving as an interpreter and negotiator in transactions among the Dutch, Portuguese, and Cochoqua Khoikhoi.

➤ OLFERT DAPPER'S 1668 DESCRIPTION OF PUBLIC WOMEN

The Dutch geographer Olfert Dapper published one of the most objective and detailed works on Africa in 1668, *Description of Africa*. Compiled from many published and unpublished accounts of travelers, traders, pilgrims, and diplomats, the volume reflected Dapper's own cultural biases and the intensification of Dutch mercantile interest in the Atlantic trade after supplanting the Portuguese in the Indian Ocean and capturing Brazil and key West African forts. For the Upper Guinea coast to the Cape of Good Hope, Dapper provides a remarkable breadth of precolonial descriptions of African agriculture, enterprise, architecture, rulers, and women. Some accounts are so detailed and specific that they allow scholars to monitor change over time in community rituals that have persisted into the colonial era.

Dapper's detailed description of Akan public women at Axim on the Gold Coast during the

1660s remains a valuable historical source on pre-European strategies employed by West African men in order to regulate female sexuality. As distinct from forms of prostitution later introduced, public women provided sexual services to unmarried males. Their institutionalized roles were as conscripted public servants under the control of male elders. Often originating as slaves, the women were given the ability to take food and other goods from the market or any home in compensation. They were ritually sanctioned and did not accumulate wealth from the sale of sex. Yet the public women's role reinforced patriarchal control and furthered the existing social order by reducing intergenerational and other potential conflicts. Wealth and power would remain male prerogatives into colonial times.

—Candice Goucher

Converting to Christianity, Eva moved between the cultural worlds of the European African frontier, adopting dress and diet appropriate to each encounter. She eventually married a European surgeon with whom she had three children. After her husband's death, Eva was unable to preserve her precarious position between cultures. She succumbed to alcoholism and eventually died in the Robben Island prison in 1674.

The period between 1450 and 1750 brought African women in the hinterland few opportunities for contact with the wider world. For most African women, the lineage head or state remained the mediator in sexual and gender relationships. Marriage and motherhood provided the critical components toward female identity, although women were perceived to perform both reproductive and productive roles critical to society. While barren women could occasionally perform ritual roles, bearing children ensured a woman's ability to manipulate her role as wife and mother in family and community politics. Women were seldom traded as slaves because of their valued labor, and even concubines, women assimilated into households and retained primarily for their sexual services, could provide sons who would be kings, as

in the large West African empire of Songhay, where the askias were children of concubines. Elsewhere in West Africa some female slaves became warriors, as in the example of the royal guard of the Dahomean king, women soldiers known to Europeans as "Amazons."

The Akan proverb that exhorts that even if a woman possesses a talking drum (the privilege of those in authority) she must keep it in a room belonging to a man expresses the conundrum of female advantage and subordination even in a matrilineal society. Elite women such as queen mothers could wield considerable political authority over nonroyal women and men. For example, the Asante queen mother helped depose and install rulers, although she was not eligible for the highest office. Ritual scorn and ridicule also were available collectively to women, who actively challenged patriarchal decision making across sub-Saharan Africa.

Although rare, some examples of female rulers are recorded in oral traditions and written records. In the early seventeenth century a royal woman seized the throne of Matamba, a central African territory. Queen Nzinga ruled between 1624 and 1663, an era during which her people actively engaged in slave raiding and cyclical

warfare that spread from Portuguese-conquered lands. The seventeenth and eighteenth centuries began an era of increasing insecurity and violence, which increased female vulnerability and destabilized social structures for generations to come. Colonial systems would provide new ideologies of domesticity and subordination and new reasons for resistance.

Ottoman Wives and Concubines

As is true of most Muslim societies, custom and tradition expected every Ottoman Turk to marry. Celibacy was considered an unnatural state that no reasonable person would freely enter into and one that if forced might have disastrous consequences. The Turkish concept of sexual desire was practical; if the young remained unmarried, it was likely that their sexual desires would find an outlet outside of marriage. Since promiscuity was viewed as socially and morally dangerous, in most cases both men and women were married at an early age, often soon after puberty.

Traditionally, the parents of the couple arranged marriages for their children. Although the Turkish family structure was patriarchal, it was generally the boy's mother who was responsible for choosing her son's bride. If the girl's family agreed, the matter would be settled by the parents, and a marriage contract would be drawn up that outlined the financial obligations and personal responsibilities of the bride and groom as well as of their respective families. The primary consideration in most marriages was economic. Thus, a "good marriage" was one in which parents arranged for a mate of equal or higher social or economic status. A woman's

skill as a housekeeper and a man's ability to provide a comfortable and secure life for his wife and family were likewise carefully considered by parents hoping to make a good match for their children.

The Ottoman empire did not show the same enthusiasm for first-cousin marriages as did most other Muslim societies. Nevertheless, there were many practical reasons to promote endogamy (marrying within the tribe or family). Chief among these was that endogamy cemented the patriarchy and kept the wealth of the family intact, since inheritance and property are not dissipated among too many people. Endogamy also increased opportunities for the couple to know one another before contracting a marriage. Exogamy (marrying outside the family or tribe) had its own advantages, however, including creating or strengthening alliances and/or networks of contracts, enlarging the choice of marriage partners, and introducing new genetic information to a bloodline.

While such practical considerations weighed heavily, the happiness of the couple, including physical attractiveness, was not ignored. While in some cases the young couple might be complete strangers to one another, occasionally the match was as much about existing romantic feelings as it was about the practical economics of the union. If for whatever reason the families did not approve of their children's personal choice, a young couple might consider *kiz kacirma* ("stealing a bride"), which was essentially a form of elopement. The boy would come to the girl's house at night, and they would sneak away to the house of a friend or relative. As long as a boy and girl spent the night together they had to marry, regardless of whether or not the couple had actually engaged in any sexual activity.

Islamic law allows a man to marry up to four wives as long as certain conditions are met, the main concern being equality of treatment. For most of Ottoman history, it has been estimated that only 5 percent of women were polygamous wives. Among the common people, polygamy was primarily a form of social welfare by which men would take responsibility for women who might otherwise have no opportunities. For example, a man might marry and provide for the wife of a dead brother or take a second wife if

THE SULTANATE OF WOMEN

The rise of the imperial harem and the so-called Sultanate of Women in the sixteenth and seventeenth centuries was one of the most dramatic developments in Ottoman history. During this period the mothers, wives, and concubines of sultans enjoyed unprecedented political power and public prominence. Of particular importance were the Valide Sultan, the mother of the reigning sultan, and the Haseki, the favorite concubine, who ruled alongside or manipulated capable sultans and ruled in place of young or incompetent ones. These were highly intelligent women who were responsible for creating and successfully maneuvering political factions at home and abroad. As the richest and most powerful of the imperial women, the Haseki and particularly the Valide Sultan also played important cultural roles. They were royal patrons and philanthropists and participated in public rituals that legitimized the continued rule of the Ottomans.

The first of the Sultanate of Women was Hurrem Sultan (1521–1558), who broke several imperial traditions during the reign of Suleiman I, “the Magnificent.” She bore him five sons rather than only one, stayed in Istanbul with the sultan instead of accompanying her sons into provincial governorships, and eventually enjoyed a change in status from that of a slave concubine to a wife. Succeeded by her daughter-in-law, Nurbanu (1574–1583), another concubine turned wife, this second powerful imperial woman firmly established a paradigm for the political and personal careers of later Valide Sultans, including Safiye (1595–1603), Kosem (1623–1651), and Turhan (1651–1683).

—Julie T. Abouzelof

his first wife proved sterile. Periods of intense warfare seriously depleted the amount of single men, and thus polygamy allowed every woman a chance to marry. Of course, among the rich and powerful, polygamy was often simply a matter of a man wanting more than one woman.

Islamic law also allows a man to have an unlimited number of concubines. Concubines were almost always of a lower social status than wives and did not enjoy the same legal protection and social respect of a wife. But because the

relationship was public and quasi matrimonial and any children conceived were considered legitimate, concubines had a higher legal and social status than that of a mistress. The marriage and succession policies of the Ottoman ruling family changed significantly over the course of the dynasty's rule. The first two sultans, Osman (r. ca. 1299–1324) and Orhan (r. ca. 1324–1361), married women from other important families and were succeeded by their sons. Under the leadership of the third sultan, Murad I (r. 1361–1389), marriage and succession policies began to change. The practice of slave concubinage became a reproductive principle for the dynasty in the fourteenth and fifteenth centuries, meaning that virtually all offspring of the sultan were born to concubine mothers. This served to emphasize the patriarchal nature of Ottoman political power, because slave concubines, unlike wives, have no formal lineage. Thus, the Ottoman Royal House was not beholden to or allied with any other strong dynastic family, since no women with important family connections married into the Ottoman dynasty. During the mid-sixteenth century, however, the imperial sexual policies reverted back to marriage, although concubines continued to fill the imperial harem to provide for the sexual needs of the sultan and display the opulence of the dynasty.

Private Sphere, Public Sphere in China

Scholars have long debated the relationship between the private sphere and the public sphere in Chinese history. Whether or not academics

find the term appropriate to Chinese history depends largely on the definition of “spheres.” It can be argued convincingly, nonetheless, that China’s “public sphere” has been in existence since at least the sixteenth century, when both merchants and gentry actively sought to influence public policy and activities.

According to German philosopher Jürgen Habermas, the private sphere entails an individual’s home life and personal financial pursuits. Free markets, therefore, are integral to the private sphere, enabling the individual to pursue financial goals for personal benefit. In the case of sixteenth-century China, merchants are the most obvious examples of individuals functioning with the private sphere. At this time China’s merchant class flourished, especially in the Hui-zhou region, where traders developed thriving businesses and represented the majority of the population.

By contrast, Habermas explains that the public sphere is an arena in which private individuals voluntarily form public but nongovernmental associations. In other words, the public sphere possesses a high degree of autonomy from the state and uses that autonomy to influence, perpetuate, or reform the state. Some scholars, such as Frederic Wakeman, claim that the concept of a public sphere is uniquely Western and therefore incongruous with China’s situation. Others, including Timothy Brook and B. Michael Frolic, contend that while the public sphere paradigm creates a challenge for understanding China, it is nonetheless instructive and useful in making cross-cultural comparisons. Still others, such as Bryna Goodman and Philip Huang, choose to avoid the term altogether, using less precise and value-laden terms such as “middle realm,” “third realm,” or “civic ground” when discussing China.

Regardless of whether we call it a civic ground, a middle realm, or some other such term, there was a burgeoning public sphere during the late Ming period (1368–1644). By looking at the roles of the merchants and the gentry of this period, it is possible to understand better the complex relationship between the public and private spheres in China.

During the Ming, scholars occupied the most elite levels in society (followed, theoretically, by

➤ WANG DAOKUN, LIVES OF EMINENT MERCHANTS

Wang Daokun (1525–1593), one of the most well-known merchants of the sixteenth century, exemplifies the role of the merchant-gentry within China’s public sphere. Wang’s grandfather was a relatively poor peasant who worked the land. According to Confucian tradition, peasants—regardless how poor—were higher on the social ladder than merchants. Nevertheless, Wang’s grandfather turned from farming and started a career in commerce. Within a few years he had gained enough wealth to acquire the trappings of the gentry elite, thereby raising the family’s status. At the same time, the family pursued the more traditional route to status, with Wang studying for the civil service exams.

Rather than hiding his merchant background, Wang relished in it. In his writings he valorized the process of obtaining wealth through commerce, portraying it as the ultimate act of Confucian honor and loyalty. By the end of the sixteenth century, mercantilism was no longer considered a distasteful pursuit but was seen as one method (and perhaps the preferred method) for maintaining a family’s status and exerting influence within the public sphere.

—David Kenley

peasants, artisans, and finally merchants). Accordingly, to become a government official, an individual needed to pass a rigorous series of civil service examinations. The curriculum for the examinations consisted of the Confucian classics, official dynastic histories, and philosophical commentaries. Many viewed the exam candidates as defenders of China’s cultural heritage. Once you passed the highest levels of the exam, the imperial court would reward you with a government position. Competition was severe. Because of strict government quotas, only about 1 out of every 6,000 individuals who took the first exam eventually earned a government position. This helped ensure continuing prestige for those who succeeded, but it also led to crucial understaffing for the bureaucracy. Usually the lowest-level bureaucrat, the district magistrate, was responsible for governing over 100,000 individuals.

Not surprisingly, thousands of individuals invested years studying for the exams but never passed them. Rather than becoming government officials, these individuals joined the gentry class, functioning as unofficial mediators between private individuals and the state's official representatives. Because the bureaucracy was understaffed, the gentry provided crucial services within the public sphere, helping to organize groups and projects for the betterment of private individuals. Members of the gentry class would often adjudicate disputes, organize flood control, establish famine relief projects, and enlist individuals for village defense. Like their bureaucratic counterparts, they also served as defenders of the Chinese tradition. In addition to their education, the symbols of their power included large libraries, impressive gardens, and collections of rare art.

China's amorphous public sphere was further complicated by the existence of powerful and wealthy merchants. According to Confucian tradition, merchants were the lowest level on the Chinese social ladder because pursuit of profit was considered adversarial and unseemly. However, as is true in all philosophical traditions, reality and theory did not always coincide. During the Ming period, many merchants prospered. In the Huizhou region (situated between Jiangsu and Zhejiang provinces), salt merchants and pawn brokers became legendary. Traveling long distances in the pursuit of trade, Huizhou merchants epitomized the individual freedom of the private sphere. Nevertheless, these merchants also played a pivotal role in China's public sphere as well. To supplement their power, many merchants acquired the trappings of the gentry elite, including libraries of rare books, collections of famous Tang dynasty paintings, and fine porcelain. They would also use their accumulated wealth to send their sons to the best schools, hoping that they would be able to pass the civil service exams and bring added respect to the family. Such merchants served dual functions as both private merchants and semipublic gentry.

For all these reasons, the division between the state and the private individual remained fluid and imprecise in Ming dynasty China. Instead, there was a public sphere—an area of autonomous organization beyond the control

of the imperial household—dominated by members of the gentry and aspiring gentry of the merchant class.

Ladies of Quality—Ideals of Womanhood in the Early Modern West

Chastity and obedience characterized ideal womanhood in Europe's early modern period. A proper woman was submissive, her speech was restrained, and her appearance was modest. As the weaker sex, women were considered vulnerable. They therefore yielded to their husbands and fathers who, as men, were more experienced with the world and could provide protection from it. In short, in all of their actions, from

the home to the marketplace, women were to comport themselves with modesty and meekness. While these ideals characterized women throughout the period, by the end of the eighteenth century a significant shift in their perception was beginning. For women in the early part of the period, maintaining feminine virtues was considered a daily struggle, as women were thought to be inherently weak with a penchant for wickedness. Virtue had to be cultivated and did not come naturally to women. As the divide between public and private became more pronounced, though, feminine ideals took on an increasingly moral tone, and women began to be seen as naturally inclined toward chastity and morality. Femininity had increasingly positive connotations as womanhood became synonymous with virtue and domesticity.

These social ideals were best expressed in prescriptive literature from the period. Aimed at the elite, prescriptive literature provided women and men with guidance for ordering their daily lives and achieving the ideals of their sex. For men, these works centered on how best to order a household and conduct business. The works designed for women, though, instructed them to be deferential to their husbands and offered advice on how to dress modestly and choose appropriate topics for conversation. Richard Braithwaite, who penned the handbook *The English Gentlewoman* in 1631, instructed women always to keep thoughts of virtue and modesty in their minds and to dress and speak in a like manner. To reinforce these feminine virtues, works such as Braithwaite's advocated education in feminine skills such as needlecraft, painting, and dancing. Elite women commonly learned to read and write, but their education was usually not extended much beyond a basic knowledge. Other subjects were considered not only too difficult but also inappropriate, as too much education could hinder a woman's chastity.

Women's real lives, of course, contradicted these ideals at every turn. Contemporary to Braithwaite's handbook were works by Aphra Behn (1640–1689), regarded by many scholars as an early feminist, who wrote treatises defending the female sex. Contemporary letters between husbands and wives also demonstrated that women frequently did not conform to the

> A GUIDE FOR GENTLEWOMEN

The English Gentlewoman, published in 1631, was a popular conduct book for aristocratic and upper-class women that gave women instructions and advice for ordering their lives. Written by Richard Braithwaite (1587/1588–1673), an Oxford- and Cambridge-educated writer, the book was quite popular in its time, as was its earlier companion piece, *The English Gentleman*. Both works went through several reprints and editions. For *The English Gentlewoman*, Braithwaite listed his prime subjects as “Apparell,” “Behaviour,” “Complement” (“What Complement gives best accomplishment”), “Decency,” “Estimation” (“My prize, is her owne praise”), “Fancie” (“How it may be checked, if too wilde”), “Gentilitie,” and “Honour.”

—Katherine E. Worley

(Folger Shakespeare Library)

notions of submission and silence laid out in prescriptive literature. In letters to her husband Robert, for example, Lady Brilliana Harley frequently gave her opinion regarding local and national politics. Also, it was not uncommon for elite women to be highly educated. In the sixteenth century, Lady Jane Grey (1537–1554) was renowned for her knowledge of languages, and Queen Elizabeth I (1533–1603), while indeed quite skilled at playing the virginals, was also well versed in Latin and Greek. By the eighteenth century, instruction in these classical languages was more commonplace, as schools for girls sprang up throughout cities such as London and education became more accessible for the daughters of middling-class families.

Western Concepts of Masculinity

In Europe's early modern period, the concept of masculinity evolved from its medieval roots, in which martial violence was cast as a characteristic of maleness, to a new model that emphasized men's intellectual capabilities. This shift did not, however, completely overturn traditional patriarchal beliefs. Although the reforms of Protestantism restrained the culture of male dominance to a limited extent, the subsequent rise of colonial empires, capitalism, and centralized nation-states created countless opportunities for the consolidation of masculine authority. The model of masculinity that developed during the period from 1500 to 1800 endured with little alteration until the twentieth century, when the women's rights movement fostered more egalitarian notions of gender.

Issues of gender and sexuality were hotly contested during the sixteenth and seventeenth centuries, the era of the Protestant Reformation and Catholic Counter-Reformation. Martin Luther (1483–1546), John Calvin (1509–1564), and

other Protestant leaders challenged traditional notions of gender, including the Church's doctrine that sex within marriage was a necessary evil. Instead, reformist thinkers asserted the novel view that marital sex could be a joy and a blessing for couples to share. This new attitude, together with Protestant advocacy for the right to divorce, helped to soften some of the misogynous elements of Christianity. Scholars such as James Brundage observe that although they certainly did not see women as men's equals, most Protestant leaders believed women to be sacred to God and eschewed the medieval conception of women as inherently wicked creatures who were mired in sensuality and materialism.

During the Reformation, however, the Catholic Church remained firmly entrenched in its male-dominant worldview. At the long-running Council of Trent, which began in 1545, Church leaders reiterated their prohibition of divorce. Clerical marriage, another Protestant cause, was rejected, and after the council closed in December 1563, the Church decreed that men of the cloth would face severe penalties for violating their vows of celibacy.

Protestants and Catholics did maintain a consensus on some issues of gender and sexuality during this period. Both groups, for example, prosecuted prostitution and homosexuality more fervently than had been customary during the Middle Ages. These prosecutions accelerated as both Protestants and Catholics strove to prove that they upheld higher moral standards than their opponents. And although the Reformation-era religious upheavals spawned such terrible conflicts as the horrific Thirty Years' War (1618–1648), in general the various denominations of Christianity acknowledged and strove to reduce the problem of the masculine impulse toward violence during this period.

From the end of the Middle Ages there was a steady erosion of the belief that prowess, or skill and valor in battle, was the quintessential masculine trait. As early as the fourteenth century, writers such as Geoffrey Chaucer and John Gower were expressing grave concerns about the ethos of warrior masculinity and its deleterious effects upon society. Historians such as David Rosen have traced this shift by examining literary works spanning from the Middle Ages to

► SIMPLICIUS SIMPLICISSIMUS AND EARLY MODERN MASCULINITY

One product of the Thirty Years' War that indicated the rejection of an older vision of masculinity grounded in military prowess was the picaresque novel *The Adventures of Simplicius Simplicissimus* (1668). The author, Hans Jakob Christoffel von Grimmelshausen (1621–1676), provided a graphic yet satirical portrayal of the war in which he had served as a common soldier. The novel is a fascinating study in early modern masculinity, as it recounts how a naive young boy evolves into a wise, devout Christian. In the following passage, the hero describes how his participation in the war corrupted him and transformed him into a kind of monster:

“Eventually I began to lead an Epicurean life, eating and swilling, for there was no one who would tell me off or whom I'd have to mind. The

officers joined me in malfeasance by enjoying my payoffs, and those who should have punished and corrected me encouraged me in further vices. Finally I became so godless, bold, and despicable that there wasn't a piece of roguery I wouldn't have tackled.”

By the end of the tale, shipwrecked on a deserted island, Simplicius, after renouncing his worldly ways, finds inner peace and the hope of salvation as a man of God.

the seventeenth century and noting how a masculinity rooted in physical strength and violent action found in texts such as *Beowulf* (ca. 1000) gave way in *Hamlet* (1600) and then in Milton's *Paradise Lost* (1674) to a masculinity based upon a different kind of prowess, the capacity for reason.

As men of reason from the Renaissance through the Enlightenment expanded the frontiers of human achievement, they concomitantly expanded the frontiers of masculine authority. The foundation of colonial empires, for instance, was oriented around such traditionally male domains as war and sea-based trade. Similarly, R. W. Connell and other scholars see in the seventeenth and eighteenth centuries the rise of market-based capitalism and centralized national governments, both of which created a vast array of new careers and social roles but only for men, who used their privileged place atop the gender hierarchy to seize these opportunities.

With the end of the Enlightenment came a gradual but sweeping change in how people perceived male and female bodies. The one-sex theory—the idea popularized by the late classical physician Galen that women's sex organs were simply an inverted version of male

anatomy—gave way to the modern understanding of two essentially different sexes (sexual dimorphism). The one-sex theory had survived the rise of empiricism in the Renaissance, as Thomas Laqueur describes, because even though medical scholars could see that men and women were anatomically distinct, the notion that women were defective men was so ingrained in the culture that ideology trumped observation. By circa 1800, though, most scholars had come to accept the theory of sexual dimorphism. Men still believed in the superiority of the male, but now their justification was biological rather than cosmic or spiritual. Women were held as inferior because of sex-determined characteristics such as the menstrual cycle, which was said to make women too unstable for participation in politics or other aspects of the public sphere.

Eunuchs in the Political Sphere

Eunuchs (castrated men) have played a role in politics, religion, and society in much of the Eurasian ecumene since antiquity, particularly in the late Byzantine empire and China. From 1450 to 1770 they were an integral part of the Ottoman, Mughal, and Chinese (in both the Ming and Qing ruling dynasties) administrative institutions and military apparatuses. While castration was generally frowned upon by these myriad societies due to strict religious beliefs on genital mutilation, eunuchs were able to acquire an immense amount of power as high officials working for the imperial ruling elites, and working in harems in close interaction with the royal

household. Culturally based gendered assumptions of eunuchs (amenability due to their lack of “manhood” and their “effeminate” nature) as well as their inability to procreate supposedly made them reliable political administrators and trustworthy military officials in these realms. However, these supposed qualities were not often grounded in actual reality, as many eunuchs were ambitious and in some instances the actual locus of power.

Eunuchs in early modern societies were either slaves or the young sons of poor peasants who had their testicles smashed or removed, with the intention of ending their ability to procreate for the purpose of entering into government office. There were instances where the penis was also removed and thereby ended all sexual functions, but in cases where only the testicles were removed the eunuch was still able to function sexually. However, due to the nature of the wounds and the high rate of infections, particularly in regard to the severed urinary tract when the penis was removed, some eunuchs did not survive the procedure. Prepubescent eunuchs would tend to have a different physical development (e.g., high-pitched voices, physiognomy, and body hair growth) into adulthood in relation to normal men due to their lowered testosterone levels, giving them what was assumed to be less masculine characteristics in terms of personality by their respective societies. Adult eunuchs, or those who would be castrated after puberty, would not exhibit the same level of physical developmental difference in growth. However, they did age faster and experienced declined health due to loss of testosterone.

The fall of Constantinople in 1453 to the Ottoman Turks effectively ended the Byzantine empire that had existed since Late Antiquity and was centered on the Bosphorus and Asia Minor. Some historians suggest that the Ottomans adopted the use of eunuchs as political administrators from the renowned Byzantine practice, given their alleged reliability and inability to impregnate members of the royal family. Eunuchs were divided into two types, the black and white eunuchs, who served different political functions. Black eunuchs, purchased as slaves from sub-Saharan Africa, served in the Ottoman imperial harem (seraglio) in the Topkapı Palace

► THE CASTRATI IN EARLY MODERN EUROPE—GENDER AND CULTURE

The use of castrated choir boys in the early modern Catholic Church of the sixteenth century, particularly in Italy, established the precedent for their use as opera singers in the baroque period. While European society generally frowned on eunuchs and male castration, an exception was made for the castrati. Regardless of societal conceptions of castrated men as “lesser men,” the castrati were a pivotal part of Western music in early modern Europe. These singers were castrated in their prepubescent years in order to prevent the development of their larynx and thus allow them to sing at high pitches for a prolonged period of time in church choirs or as accompanists in operas. While this was a risky procedure given the potential of infection and eminent death, the castrati were highly valued after rigorous training and with the growing popularity of Italian opera. Many famous castrati, such as Senesino, became celebrities within their lifetime, living in ostentation and having multiple affairs with aristocratic women.

—Abraham O. Mendoza

at the service of high government officials and the household concubines, all under the charge of the chief black eunuch. In the late sixteenth century the chief black eunuch was able to exert a great amount of influence over administrative functions of the realm, given the amount of time Ottoman princes and elites spent in the harem. Ottoman princes would only leave the palace harem when assuming the throne, so they were often under the guidance of the chief black eunuch. White eunuchs typically acquired from the Balkan and Caucasus provinces of the Ottoman empire were used to fill administrative positions mostly outside of the harem but were still highly valued by the ruling elites. In general, given their access to direct political power, some Ottoman eunuchs were nonetheless able to garner power and intrigue against the sultan or the grand vizier by allying themselves with rival factions actively plotting against high hereditary officials.

In China eunuchs also operated at the highest levels of government, serving the ruling dynasty as high administrators and officials. While this institution had preexisted this period in East Asia, eunuchs in China became an integral part of Ming governance, as they were initially exchanged with provinces and neighbors as forms of tribute upon the foundation of the Ming state. Over time, as in the Ottoman empire, castration became a way for people to enter government service without having to take civil service examinations. Young boys were castrated and taken into the Ming court in the Forbidden City to serve the emperor and his family in close quarters and thus became an integral part of the household. Upon gaining the confidence of the emperor and his close associates, court eunuchs served as direct representatives of the emperor, often serving as foreign envoys, administrative adjuncts, and even military officials (most notably Chinese admiral Zheng He). For instance, Ming court eunuchs served as diplomatic envoys to Korea. Due to their prevalence in Ming imperial governance, they were resented by the civil service bureaucracy (mandarins), which had to go through years of training and rigorous examinations to attain their own positions. As a result, there was much intriguing and competition between the official bureaucracy and Ming

court eunuchs, which affected the political dynamics of the court often at the expense of the emperor, who was assumed to be under the nefarious influence of the eunuchs. The position of eunuch was such a lucrative one that the imperial government declared an edict against self-castration, as sometimes over 1,000 castrated young men would present themselves to the emperor in the hopes of being selected to serve at court. The subsequent Qing (Manchu) dynasty (1644–1911), while retaining the service of court eunuchs, diminished the role of court eunuchs from involvement in politics. Nonetheless, they were still able to contribute to the administration of Qing China as part of the political milieu of court society.

Mughal India (1526–1707), much like the Ottomans and the Chinese, also relied on court eunuchs as administrators. Mughal sultans, with access to central Asian trade networks, would purchase eunuchs to serve in their courts. Many of these eunuchs served the Mughal emperors loyally but were also often in the middle of court conspiracies and political intrigue and were despised by high officials and bureaucrats as meddlers. As part of the court, they were able to influence the royal household and attain increasing levels of power while being theoretically politically (as well as sexually) impotent. The reality was that they oftentimes served in high positions under the sultan or the vizier and thus were an integral element in Mughal governance.

Homosexuality in the Early Modern World

Although the word “homosexuality” was not coined until the nineteenth century, same-sex erotic and romantic practices existed in many early modern cultures. As was the case in many other areas of life, male practices and customs

► THE MOLLY HOUSES OF EARLY EIGHTEENTH-CENTURY LONDON

Early-eighteenth-century London had a network of clubs and gathering places for gay men known as “molly houses.” “Molly” was a slang term that originally meant a female prostitute and came to mean an effeminate man. One of the largest was the house of Margaret Clap, “Mother Clap’s,” on Field Lane in the Holborn district of London. An informer’s account of an evening there suggests that 40 or 50 men gathered, many wearing women’s clothing and mimicking female behavior by curtsying and addressing each other with women’s names. Men danced together, and some molly houses had smaller rooms for intimate encounters. Mother Clap’s was a private house, but many molly houses were connected to taverns, and the sale of alcohol provided their economic foundation. Many of these men were married to women and maintained masculine personas outside the molly house.

Molly houses were targets of periodic crack-downs organized and encouraged by the Society for the Reformation of Manners, a private group protecting England from God’s wrath by rooting out sin. In the purge of 1726 three “mollies” were executed, and many more imprisoned, fined, or made to stand in a pillory while London citizens threw things at them.

—William E. Burns

are far better documented than female ones. The male literacy rate was higher, and men were more likely to find themselves in legal trouble that led to the creation of court records.

Both male and female homosexuality were frequently marked by the adoption of cross-gender behavior. Some societies institutionalized mixed gender roles, although transvestism or transgenderism did not always lead to homosexuality. One such instance can be found in the *hijra* of India, a group of people who are mostly biologically male and usually dress as females but are considered a third gender, neither male or female. Unlike transgenders in the modern Western world, the *hijra* do not attempt to pass themselves off as the opposite sex, but many do have relationships with other males. Another example exists in many Native American and Canadian First

National societies; a generic term for this is *berdache*. These individuals are considered to be living as people with two souls inside of them, one female and one male. The possession of these two spirits allowed for berdache to perform societal roles of both genders, although female-bodied berdaches normally had relations only with other females. European societies did not have similar socially sanctioned roles. However, evidence of transvestite behavior among males was found in underground homosexual societies such as the London molly houses, private rooms or taverns where homosexual males and transvestites could meet in order to find sexual partners. Many African societies show evidence of fluid marital relationships involving women. Some women, although already married to men, were powerful and wealthy enough to buy “wives,” whose roles seem to be those of mere servants. However, any children born to these wives were the legal right of the woman who had paid the bride price for them, not the biological father. Other women obtained husbands who were biologically female, or “female husbands,” for a variety of reasons, some of which seem to be greater companionship, in order to avoid domestic violence, or to obtain a higher bride price often paid by female husbands. In addition, it was not unusual to find “male daughters,” especially in families where no sons survived. A ritual was performed in which the gender of the female was changed to male, thereby permitting the new male to inherit the family estate. However, once a female was identified as a male either by being a female husband or a male daughter, she was then expected to participate in the society as a male.

In the absence of social role models for lesbian relationships in Europe, some women, such as the abbess Bendetta Carlini (1591–1661), seem to have found it necessary to think of themselves as men in order to love women, although in retrospect it is often difficult to distinguish between a masculine-appearing lesbian taking a male role and a female-to-male transgendered person such as the seventeenth-century Spanish American soldier and muledriver Catalina d’Erauso. Female-to-male roles were usually not institutionalized the way male-to-female ones were, although there is evidence of a “manlike woman” social role among some Native American groups.

An alternative to transgenderism as a way of organizing male-male relationships was by difference in age, with the older partner usually viewed as the “active,” penetrating partner and the younger as the “passive,” penetrated partner. In Europe, these relationships were associated with the humanist tradition and the revival of ancient Greek literature, including homoerotic literature, in the Renaissance. The image of Ganymede, the beautiful young boy carried off to Olympus by Zeus, chief of the Greek gods, was particularly strongly associated with pederasty and was frequently referred to in literature and art. Notable paintings of Ganymede’s kidnapping include those by Correggio and Rembrandt. Humanistic schoolmasters, trained in Greek and with the responsibility for teaching boys and young men, were often suspected of sodomy. The love of an adult male for a beautiful youth frequently appears in literature, with perhaps the best-known example in the early modern period being the sonnets of William Shakespeare. The legendary love between Sultan Mahmud of Ghazni and his young male slave Ayaz was frequently referred to in Persian literature.

All European countries strictly forbade same-gender sex, or sodomy. The degree to which the prohibition was enforced, however, varied greatly, although the state was always more concerned with male homosexuality than with female homosexuality. Although lesbianism was subject to the death penalty in the *Constitutio Criminalis Carolina* of the Holy Roman Empire, promulgated in 1532, the few cases where the penalty was actually applied usually involved aggravating circumstances, such as cross-dressing or the use of a dildo or other instrument to counterfeit the penis. The Protestant and Catholic reformations, with their emphasis on building godly societies, led to increased hostility to homosexuality. Sodomy, Italy, and Catholicism were often linked in Protestant propaganda, which also charged that single-sex convents and monasteries were hotbeds of homosexuality. This hostility to monogendered religious environments would be taken up by the European Enlightenment in such works as Denis Diderot’s *The Nun*. Certain religious orders, such as the Jesuits, would acquire particularly strong reputations as predatory homosexuals. As the Jesuits combined the

culture of a celibate religious order with school mastering, this was unsurprising. Crackdowns on male homosexuality, like the anti-molly house campaign in England in 1726 and the Dutch Republic’s campaign from 1730 to 1732 that led to dozens of executions, were often placed in the context of appeasing an angry God. However, there were long periods when society turned a blind eye to same-sex relationships. Despite the obloquy targeting homosexuality, several European monarchs during this period, including Henri III of France, James VI and I of Great Britain, and Christina of Sweden, engaged in more or less open homosexual affairs.

Homosexual sex was also forbidden by Jewish law and by the Sharia law of Islam, although interpretations and punishments differed between the major Sunni schools of Islamic legal interpretation and between Sunni and Shia. Some schools distinguished between the penalties due to the active and the passive partner.

Although Chinese law had previously been indifferent to homosexuality, in 1740 an imperial decree criminalized consensual sex between men as part of a general movement under the early Qing dynasty toward enforcing the norms of the Confucian family after what was viewed as the laxness of the late Ming. (Ironically, the Qianlong Emperor [r. 1736–1795] would later be attacked for his intimacy with his male favorite, Heshen.) The extent to which the law was enforced, however, is unknown. The Confucian rulers of Vietnam, whose legal codes were greatly influenced by China’s, did not follow the Chinese example and have never outlawed homosexuality. Japan had a vigorous male homosexual culture in this period. Like Europeans, Japanese associated monasteries with homosexuality, although Japanese monastic homosexuality was far more open. Homosexuality was also found in the warrior culture of the samurai and the theatrical world of the Kabuki, as shown in the works of the “floating world” novelist Ihara Saikaku (1642–1693), including *The Great Mirror of Male Love*.

European expansion in this period led to contact with many societies that were less antihomosexual than Europe itself and had a sanctioned and even public role for same-sex relationships. European Christians reacted by

claiming that open sodomy was evidence of the power of the devil over Native American and other homosexuality-accepting societies, and the suppression of deviant practices was a justification for European conquest and forcible suppression of indigenous cultures. However, marginal and frontier societies with a premium on male violence often led to the formation of homosexual subcultures among European men, such as the pirates of the Caribbean.

A Pirate's Life for Me—Sixteenth-Century Shipboard Conditions

While there was a great deal of disparity, shipboard conditions in the sixteenth century were generally appalling by modern standards. Ships, especially the larger ones, were crowded, and manning rates were high compared to later periods, in part because sailing ships required a great deal of manpower but also because mortality and morbidity were elevated on long-distance voyages.

Only the highest-ranking officers could be guaranteed their own cabins. On larger vessels common seamen were usually well below decks, where ventilation and conditions were extremely poor. Hammocks were introduced during the course of the sixteenth century in European ships, and this improved sleeping arrangements somewhat.

Because fresh water was a treasured commodity on shipboard, few washed their bodies or clothing. Levels of cleanliness were low among populations on the land as well as at sea, and they varied from ship to ship and person to person.

Officers would have had the means to buy more clothes than the common seamen. Wills demonstrate that many officers carried sizable wardrobes with them, while the rank and file had little more than the clothes on their backs. There

were many complaints that seamen's clothing was worn to tatters quickly, and it was not the norm to receive a uniform or clothing allotment.

Lack of cleanliness and inadequate clothing were only two factors that made shipboard life difficult. Increasing levels of morbidity and mortality were an unhappy by-product of European expansion. Some routes were known to be more hazardous to the health of the crew due to that duration spent at sea and hostile climates. The majority of deaths resulted from fevers such as yellow fever and malaria as well as scurvy, smallpox, and "fluxes" (dysentery mainly). A small number of seafarers were shipwrecked or drowned or suffered injury on board. Even among those engaged in maritime warfare (pirates, privateers, and naval seamen, for instance), disease was the greatest killer.

Anecdotal evidence suggests that the most lethal disease was scurvy ("the plague of the sea"). Most seamen's diets were woefully inadequate in vitamin C; this could lead to painful symptoms and death. Some astute seamen noted that citrus fruit cured scurvy in the sixteenth century, but the remedy did not gain widespread acceptance for centuries.

Men on coasters that sailed close to land would have had better access to fresh provisions than those on long-distance voyages (which were provisioned for months or years). Part of the problem was the inadequacies of that age's systems to preserve food and drink. Furthermore, the modern notion of a balanced diet did not exist yet. There were variations in diet according to region, but items such as salted meat or fish, biscuit, and beer figured prominently in seafarers' diets. Fresh fruit and vegetables were rare.

In theory, the quantity of victuals was usually adequate to the high-caloric needs of these laborers of the sea (at least early in the voyage); the quality, however, often left something to be desired. Rotting food and putrid drink were common. As the voyage continued, difficulties with reprovisioning could mean that rations would be cut back. Not surprisingly, officers (and possibly other seamen) brought their own supplies to supplement their meals. Even when seamen were given their full allotment of victuals, meals were normally monotonous and lacking in many essential vitamins.

Provisioning large numbers of men in a fleet was especially complicated in terms of not only preservation but also acquisition and monitoring of quality. One had to worry about the natural hazards such as rats and leaks aboard as well as other hungry seafarers stealing provisions. The duration of voyages were frequently unknown (especially for voyages of exploration), which caused additional problems. In extreme cases, seamen ate rats and drank their own urine.

Only a few ships carried surgeons, and sixteenth-century medical care was rudimentary at best. Surgeons were best suited to treating external injuries and battle wounds (often with amputation and without anesthesia). However, disease continued to be an overwhelming problem for several centuries, and surgeons were perplexed about the cause and treatment. Nursing the sick generally fell to fellow crewmates, or if possible the sick and injured were taken ashore for care.

Seafaring was generally a young man's occupation, and life expectancy was low on long-distance voyages. The most risky journeys were generally the most lucrative. Long-distance merchant voyages frequently offered high wages. On privateering voyages, seamen sailed for shares of prizes. Remuneration varied widely, but such voyages remained immensely popular, as seamen favored loose discipline and the possibility of lucrative prizes. This is also true of piracy. Naval service was the least popular form of seafaring employment due largely to low wages and rigorous discipline. Impressment was used to compel men to serve in the navy.

Some efforts were made to improve shipboard conditions during the sixteenth century because seamen deprived of their basic needs might resort to mutiny, and sick and hungry men usually failed to accomplish naval and mercantile goals. Efforts to improve shipboard hygiene and seamen's welfare were usually a result of individual commanders or companies. Many states resorted to impressment to force men to serve in the navy regardless of conditions. This deprived seamen of their traditional freedom to assess shipboard conditions before entering into an employment agreement and was thus deeply resented.

Gender and Morality— Eastern Europe

From the fifteenth century to the seventeenth century, gender roles in eastern Europe, both Slavic and Ottoman, were highly bifurcated and became increasingly restrictive for women in particular. Women in early modern Slavic (particularly Russian) and Ottoman societies, while retaining a semblance of agency over social and political affairs, were nonetheless relegated to the confines of the family household. Orthodox Christianity and Islam as practiced in eastern Europe stressed the necessity to remove women from the social world of men to preserve their morality and dignity, which prevented them from attaining any direct political or social power. However, within their respective households both Ottoman and Slavic women maintained considerable amounts of influence and agency. Elite women, particularly the nobility, had significant influence in the political sphere through their husbands, sons, and fathers.

Women in early modern Muscovy (state preceding Russia) were not allowed the same political, social, and economic agency as that of men and were subordinated to a lower status. However, this was to some degree contingent on social class. Serf women were subject to the drudgery of everyday life to the same degree as that of their husbands while simultaneously having to maintain their households. As lower-class women, they were not expected to escape the duties of work and were in the company of men on a daily basis. On the other hand, women in the ranks of the nobility were expected by both Russian society and the Orthodox Church to live

► CONCUBINES IN EASTERN EUROPE

Polygamy was an expensive familial arrangement for Muslim men, many of whom were reluctant to have multiple wives due to the financial obligations involved in providing for them. However, the institution of concubinage allowed Muslim men in the early modern Ottoman empire to secure the affections of another woman within his household who could give him children but was not bound to him in the same way as a wife. Concubines were not as costly as wives in that they did not expect the financial benefits of marriage, such as dowry and bride price. Some Muslim wives were not opposed to having their husbands acquire concubines, as they held a position of authority over all women in the harem as the legitimate wife. Many concubines in the Ottoman empire came as

slaves from the Black Sea provinces, either taken or sold by their parents. As European women, they were prized for their light complexions and exotic phenotype. There is evidence to suggest that many young women from the Black Sea region actually looked at their bondage as an opportunity to escape the drudgery of life in poverty-stricken regions and marry a rich Turkish pasha in Istanbul. However, as concubines they were restricted to only being servants of the household and to bear children for the Muslim man of the household. The rise of the secularizing Young Turks at the end of the nineteenth century eventually put a stop to this peculiar practice that had survived since antiquity.

—*Abraham O. Mendoza*

in a particularly stringent subservient role. They were expected to dress modestly, cover their heads, and never leave the home, especially after marriage. Married women were expected to refrain from having outside contact due to fears of infidelity and immorality. They were relegated to a section of the house known as the *tehem* in which they were expected to perform household duties such as knitting and preparing food while slaves did the heavy lifting. This did not prevent men from frequenting brothels and having mistresses, as they were not expected to live up to the same moral standards as that of women. Young Russian women were usually expected to marry early, between the ages of 12 and 16, through prearranged marriages to men considerably older than them. Passing from a position of subservience from their fathers to their husbands restricted their access to any sort of direct political and social influence.

Ottoman women in eastern Europe were also subjected to similar roles as that of their Russian counterparts. They too were married off early to men older than them. They were subject to stringent Islamic regulations regarding their public lives, meaning they were forbidden to have one. Once married, they were expected to remain confined to the harem. While men could have multiple wives based on their economic capacity to afford more than one

in addition to concubines and slaves, women could not have more than one husband. Further religious and societal restrictions on women prohibited them from showing their faces, engaging in social functions without male supervision, and leading what were deemed immoral lives. Men were not subject to such regulations but were expected to support their wives and maintain the harmony of their households. Nonetheless, the primary wife of the household did have considerable power within the harem. All of the other women of the household—other wives, concubines, slaves, and daughters—were subservient to her.

Both elite Russian and Ottoman women, while socially and politically subservient to men, did have indirect power over men in their family. While they were expected to confine themselves within the household to ensure proper moral behavior expected by their respective societies and religions, their control over their households in the absence of their spouses allowed them access to considerable legal rights, property, and divorce. While divorce was frowned upon by both the Orthodox Church and Islam as immoral, women were able to end their marriages with the help of their families if it was deemed necessary in cases of abuse or neglect or if either party failed to live up to contractual obligations stipulated in the marriage

contract. Moral conduct aside, women still retained considerable control over their daily lives.

Family and Gender in Early Modern Russia

Most Russian families during the period of the first global era were structured around a strict hierarchy within which men played a central role. Men controlled female household members, and the younger men submitted to the oldest male member of the family. All households within a community strictly observed these principles since individualist attitudes were considered inferior to collectivist ones. Moreover, the tsarist regime and the Orthodox Church supported these patriarchal attitudes since they fashioned a society that was conditioned to support both the church's and state's absolute authority. This situation was particularly evident in Russian villages, where 90 percent of the population lived. Though rural communities varied among each other, they were essentially guided by the same patriarchal principles and can best be examined through a woman's typical life cycle.

Two factors affected a woman's existence in villages: her ability to work and her ability to produce and raise offspring. During early childhood it was not uncommon that female children looked after their youngest siblings and took care of minor household chores. By the age of 12, a young peasant girl would begin her preparation to enter marriage by becoming skilled in all the household and farm work expected of an able-bodied woman. Unlike women in agriculturally advanced areas of Europe during the seventeenth and eighteenth centuries who married in their early to midtwenties, Russian women generally married between the ages of 17 and

20. Early marriages were not uncommon since women were considered both an economic and a demographic resource. Though the bride's family reluctantly parted with the extra pair of hands, both the families of potential grooms and local administrators preferred, and sometimes coerced, women to enter into marriage early. Noble serf owners benefited from marriages since they created an additional taxable unit, while the groom's household was eager to acquire a new workforce for the arduous fieldwork. Once married, the young bride would join the husband's household, where her status was nominal and her situation grim.

The peasant wife and her husband would live under the same roof with three-generational multiple families. The bride would be expected to be subservient to not only her father-in-law but also to her mother-in-law and sisters-in-law. She was to also unconditionally obey her spouse; it was peasant custom that permitted husbands to instruct their wives using fists. To make matters worse, if the husband was absent or underage, the wife could face her father-in-law's sexual advances. A woman's status improved over time as she gave birth, especially to sons. Childbearing and child rearing, however, came only after household and farm work. It was not uncommon that women gave birth to up to ten children and had only three survive. The only available method of birth control was infanticide, but if a mother was caught the local authorities would subject her to a long and

Russian merchant's family of the seventeenth century, by Andrej Riabushkin, 1896. (Scala/Art Resource, NY)

➤ SOLDATKI

The universal military draft that Peter I instituted in 1705 had a profound effect on village life in general and the lives of women in particular. Peter the Great's national draft conscripted millions of able-bodied village men into army service for life. The wives of men who were enlisted were known as *soldatki* (soldiers' wives). As their husbands were performing a state service, *soldatki* became legally free, emancipated serfs. As such, however, they often lost their husbands' share of communal lands. The fates of soldiers' wives varied. Some remained in the villages and, if they were not reduced to begging for alms from other villagers, were supported by the husbands' families or their own relatives. Often, however, as *soldatki* were seen as simply additional mouths to feed, they were driven away from the village. Many *soldatki* migrated to cities and there engaged in either petty

trade or became domestic servants. Quite a number of soldiers' wives turned to prostitution to alleviate their challenging situation. During the eighteenth century, illegitimacy and infanticide rose significantly enough to become commonplace, and Russian authorities often identified *soldatki* as one of the sources for these two phenomena. To remedy the problem, both Peter I and Catherine II established homes and hospitals to preserve the lives of their illegitimate subjects. Mothers of illegitimate children, on the other hand, received no charitable assistance from the state, as the authorities condemned and repressed any woman suspected of engaging in vice. Thus, though the state was directly responsible for causing the problematic situation that confronted millions of Russian women, it did little to alleviate their predicament.

—Marko Dumancic

painful execution. Eventually, though, usually at the death of the father-in-law, a woman could establish a household together with her husband. She would then be able to distribute work duties to the female half of the household. But again, the wife's role and status in the village depended on her spouse. If she became a widow, her husband's lands would either be repossessed by the community or taken by her sons. Consequently, a widow's usual option was to remarry as a means of keeping the household she waited a lifetime to earn.

The *Domostroi* (Household Order)—a sixteenth-century household primer—and the Law Code of 1649 were the two basic documents that enumerated the fundamental rules within the urban family. According to the *Domostroi*, the father was supposed to take complete responsibility over his wife and children, instructing them in all matters moral and worldly. The family members, in turn, were to submit to him in blind obedience. While the father was only morally obligated to his family members, the children were legally bound to obey both parents. Not only could children not raise grievances against their parents, but they were also officially subject to flogging for striking their parents, swearing at them, stealing

their property, or refusing to take care of them in old age. Parents, on the other hand, were thought to have exceeded parental privileges only when they murdered their children and even then received only a sentence of one year in prison. If a wife killed her husband for whatever reason she was to be buried alive, while a husband who killed his wife without justification was sentenced to death by decapitation. And even though there were changes in the law code that restricted the absolute power of the patriarch over other household members, the supremacy of the household head was not substantively undermined throughout this period.

Print Culture in the Early Modern West, 1400–1800

Historians continue to debate the ways in which printing influenced the development of Western culture, but the centrality of print in the history of

the West is beyond doubt. As an invention, printing is perhaps unrivaled in its cultural impact. From its creation in the mid-fifteenth century, printing remained the most important method of reaching a mass audience for 500 years.

The development of printing is unique in premodern Western history in that we actually know where and when it happened. Historians credit Johann Gutenberg (ca. 1397–1468 CE) with inventing printing in the German city of Mainz around 1450. The term “invention” can be somewhat misleading, however, as Gutenberg’s mid-fifteenth-century creation of a press with movable metal type hardly sprang fully formed from his brow. Not only did the printing press and metal type have earlier Asian antecedents, but printing from woodblocks seems to have emerged in the Germanic lands around the start of the fifteenth century.

Gutenberg’s place in history therefore should rest rather on his foresight in anticipating the popularity and profits of the mechanical multiplication of texts and on his efforts to bring together all the constituent elements necessary to do so. The printing press allowed for the spread of texts and images to anyone with disposable income, a fundamental difference from an earlier age in which only the very wealthy could afford to hire a copyist for the year necessary to write out a copy of the entire Bible.

Historians employ the somewhat arbitrary date of 1500 as the turning point in printing. More accurately, between 1480 and 1490 Western readers no longer demanded that their printed books look exactly like manuscript (handwritten) ones. They used the term “incunabula” (from the Latin *cunabula*, meaning “cradle”) to refer to printed books before the year 1500. That readers before this period preferred their books to look like the ones with which they were already familiar should not surprise us. Around 1490 the Florentine bookseller Vespasiano famously commented that within his patron Duke Federigo of Urbino’s splendid library a book produced by mechanical means would have been embarrassed to keep company with his fine manuscripts. But the preferences of the Duke 40 years after the creation of textual printing was becoming anachronistic. Printing was wildly successful, and most contemporaries

recognized its importance, including one who rhapsodized that the invention of printing was as significant for mankind as the birth of Christ.

The 1462 sacking of Mainz by warring prince-bishops was the immediate impetus for the spread of printing to other parts of Europe. Refugee German printers fled to the places where they could most profitably—and safely—set up shop. Printing presses were soon producing works in Europe’s great commercial and administrative centers: Subiaco/Rome (1463), Venice (1469), Paris (1470), Naples (1471), Valencia (1473), Bruges (1474), Lübeck (1475), and Westminster/London (1476). The London press was distinct because here a native, William Caxton, rather than a German immigrant, imported printing. Until 1470, 14 European cities possessed printing presses; by 1480, that number would jump to more than 100. Nor would printing remain limited to Europe. Presses could be found wherever Western merchants traded and settled, such as in Turkey (1503), Mexico (1534), India (1556), and Palestine (1563). This rapid proliferation of print does not imply that presses eradicated manuscript culture in the fifteenth century or indeed even centuries after. Printed and manuscript books continued to be found side by side in the same libraries. Recent research indicates that books circulated in manuscript into the eighteenth century, especially texts that secular and religious authorities found objectionable.

Political and religious authorities came to realize that print could reach mass audiences not long after merchants did but with a greater sense of alarm than opportunity. Censorship was the inevitable twin of this new mass medium, and events soon proved authorities’ concerns with censorship to be well placed. As early as 1479 Pope Sixtus IV authorized the Theological Faculty of the University of Cologne to examine printed works for examples of heresy or blasphemy. When Martin Luther sparked protests against the perceived corruption of the Catholic Church and calls for reform, print was the medium that disseminated the ideas of the resulting Protestant Reformation.

Yet early modern censorship was never as effective or efficient as the modern definition of the word implies. Contemporary authorities lacked the extensive means of surveillance and

control necessary to regulate printed materials. They usually reacted only once something offensive had been printed rather than preventing objectionable material from reaching print in the first place. These inefficiencies were exacerbated by the existence of separate bodies—secular, ecclesiastic, and economic—that were empowered to censor but only did so when it suited their interests. Last, the existence of so many polities in the relatively small area of western Europe meant that even if a local authority was successful in censoring a work printed in their domain, they were often unable to prevent banned materials being imported from other parts of Europe.

The religious disputes of the Protestant and Catholic Reformations proved especially fertile in encouraging a trade in printed contraband, such as the importing of Catholic works from the Spanish Netherlands into England or the spread of Calvinist works from francophone Switzerland into France demonstrates. Historians continue to debate the relationship between the advent of the printing press and the emergence of the Protestant Reformation. Nevertheless, it is clear that the Reformation ignited an explosion in publishing, particularly in the printing of texts in the vernacular languages of Europe. In 1517, the year that Luther published his *95 Theses*, about 40 titles were published in German. By 1519 the total increased to 111 titles, by 1521 it reached 211, the following year it exploded to 347, and in 1525 it topped out at 498 titles.

As the only effective medium for reaching a massive number of readers over a wide geographical area, print was employed extensively by both sides in the Reformation debate. The use of print in theological debate was controversial itself and helped fuel and spread the disagreements from cathedrals and university lecture halls to taverns, homes, and street corners. Furthermore, in the effort to reach as many readers as possible, reformers began to publish their works in the vernacular. These innovations shocked conservatives for whom Latin was the proper language of law and theology. Before 1500, more than 75 percent of printed material was in Latin. The publication of theological treatises in vernacular languages steadily eroded

Latin's predominance in print so that by 1600 the majority of books were printed in various forms of the vernacular.

Over the course of the sixteenth century, the German lands lost their predominance in printing as well. It is no coincidence that the rising new centers of print were also the centers of trade and prosperity, able to reach wider markets of readers who could afford printed texts. Venice, Antwerp, and Paris became the new centers of printing, and works from the presses in these cities crossed borders and spread throughout Europe on the backs of porters and in the hulls of ships.

Historians of early modern Europe disagree over the relationship between literacy and print. Did rising literacy stimulate the dissemination of print, or did spreading print boost literacy rates? The truth seems to lie somewhere in the middle, and as printing became more common, so did literacy (and vice versa) through the sixteenth century. Literacy grew at various rates and fluctuated in different parts of Europe at different times, and occasionally it also regressed. Sixteenth-century Castile provides an interesting case study, with literacy rates that rivaled or surpassed those in Northern Europe at the same time. Unlike North Europeans, however, literacy rates regressed in Castile over the following centuries, and literacy rates were probably higher in the sixteenth century than they were in the eighteenth century. The history of literacy is not always one of sustained progress but rather one of occasional stagnation and regression, even as the printed material continued to become more ubiquitous.

Most historians do agree that printing stimulated and made possible the explosion in knowledge of the early modern period, although the degree to which this knowledge was standardized and fixed is still open to debate. Regardless, learning could now spread quickly throughout Europe in a matter of months instead of years, allowing scholars to argue with and learn from contemporaries hundreds or thousands of miles away. The early modern period was a time of great upheaval in the sciences, and print helped foster this revolution. While books on science never enjoyed a wide readership and their

success was commercially ambiguous, printed materials on medicinal matters were much more popular. No doubt much of this reflects the everyday pain and health concerns that our early modern predecessors must have suffered in an age before painkillers. But the wide variety of popular and learned treatises on various topics of health and medicine suggests that there was a vigorous early modern medical culture quite distinct from the concerns of scientists and scholars.

This helps to remind us that printed books and materials were never the sole preserve of the elite and wealthy. Even day laborers could afford a single-sheet broadside or ballad every now and again. Recent research indicates that printed materials were increasingly purchased by even the poor and illiterate, who could enjoy the illustrations or have a literate friend read the contents out loud for a gathered group to enjoy. These printed images and ballads also blurred the boundaries between oral and written culture, which historians have demonstrated lived side by side for centuries.

Such findings have largely erased the distinctions between popular and elite print, as the same ballad or broadside could find a home in the seediest drinking den as well as the most refined household. This emerging market for cheap print was a boost for printers because such works could be produced quickly and inexpensively to guarantee a steady flow of income. Books, especially sizable books, largely remained the domain of the wealthy because of the high prices they commanded, however. The cost of a book was directly proportional to its size, as paper alone accounted for an astounding 75 percent of the cost of book production. High resource costs also meant that printers realized little benefit from economies of scale (reducing overall costs by producing a greater volume of books).

In understanding the importance of print in early modern culture, there is another problem that historians confront. Almost all of what was purchased by nonelite sixteenth- and seventeenth-century consumers has been lost to historians. Curiously, the survival of printed works appears to be inversely proportional to the numbers of a given work that were produced. During the incunabular period, nearly a million

single-sheet woodblock prints were probably produced, yet only about 5,000 of them survive today. Such a loss rate is staggering, as the historical record of this evidence of cheap print has been largely obliterated. Even the famous Gutenberg Bible, obviously a singular work, has only about a 30 percent survival rate.

The year 1800 serves well as a closing date for the handpress era. Beginning in England, the Industrial Revolution fueled a series of mechanical improvements that radically changed the technologies of printing. First was the perfection of machine-made paper between 1798 and 1803. The innovation was significant, reducing the cost of paper production while increasing output, and the abundance of inexpensive paper enabled printers to reap economies of scale. Coupled with changes to the printing press itself, cheap paper ushered in the true era of mass print. By 1804 the 3rd Earl Stanhope had made the first significant improvement on Gutenberg's creation by creating an iron press, which proved to be more durable and precise but not significantly faster than the wooden press. Stanhope's press did, however, allow for the automation of printing itself, significantly increasing output. After years of experimentation, a German immigrant in London, Friedrich Koenig, harnessed a press to steam power, and in 1814 the *London Times* was printed by a steam-driven press for the first time, quadrupling the daily output of a handpress. These three advances, developed together within a short time, significantly changed print culture and made the printed word an indispensable part of everyday life in the West.

Mohawk Womanhood

Mohawk society, like that of other Iroquois tribes, was organized matrilineally. Women fulfilled very specific roles that were complementary to those of men in the tribe. Each gender had its own duties, and society could not function without their cooperation. As a result, Mohawk women were raised to be confident and strong individuals.

During the seventeenth century, European observers were surprised to see the power wielded by Mohawk women. Some were confused by Mohawk government and believed that the genders

alternated governing their tribe. Europeans soon realized that in many ways, the women gave legitimacy to the men who waged wars and conducted diplomacy with other tribes and Europeans. The Jesuits who dominated the French colonial ventures during this time achieved greater influence through converting women, instead of men, to Christianity. The Jesuit practice of encouraging women like Kateri Tekakwitha to leave their villages for Christian settlements like St. Francis Xavier helped to weaken the traditional Mohawk social structure, already in decline from continuous warfare and disease.

Mohawks were born into the family of their mothers and traced their heritage through the mother's family. The matron, or head, of an extended family was usually an older woman who had proven that she could handle responsibilities. She would often be succeeded by her eldest daughter. Mohawk families belonged to different clans, and clans had branches in different villages. Husbands were selected from different clans, since members of the clans were considered brothers and sisters. Children belonged to

► KATERI TEKAKWITHA—LILY OF THE MOHAWKS

In 1980 Kateri Tekakwitha was the first Native American to be beatified by the Catholic Church, an important step on the road to being declared a saint. Tekakwitha was born in 1656 in a Mohawk settlement near present-day Auriesville, New York. Her parents died when she was four years old. The smallpox that killed her family left Tekakwitha with a deeply scarred face and poor eyesight. Her uncle's family raised her in the nearby settlement of Gandawague.

In 1667 the Mohawks allowed a small group of French Jesuit missionaries into Gandawague. Tekakwitha was assigned to take care of their needs. The priests made a special effort to instruct her in the faith. In 1669 Tekakwitha's aunts tried to arrange a marriage for her. She refused, which was very unusual for a Mohawk woman. Because Tekakwitha's husband would have become a part of her family, he would have been expected to take care of her older relatives. Tekakwitha's refusal not only went against Mohawk society's traditions but also went against the economic needs of her family. Her refusal was

apparently because of her growing interest in devoting herself to the Catholic faith.

In 1676 Tekakwitha was baptized by Father Jacques de Lamberville. Her relatives and the other Mohawks in her settlement tried to get her to renounce her faith. Tekakwitha fled for St. Francois Xavier, a settlement of Catholic Indians near Montreal. Her uncle pursued her, threatening to kill her, but she arrived safely in the fall of 1677. Tekakwitha stayed with Anastasia Tegonhatsihongo, a friend of her mother's. The two women were often in need because they had no man to hunt for them or to do heavy work. Tekakwitha still refused to marry, despite Tegonhatsihongo's pleas. Instead, Tekakwitha hoped to found an order of Native American nuns. When Church authorities would not allow her to do so, she adopted a lifestyle similar to that of a nun. She often fasted and whipped herself. Her self-penances broke Tekakwitha's health. She died on April 17, 1680. Her life and holiness were recorded by her Jesuit patrons to inspire other Native Americans.

—Timothy J. Watts

their mother's clan. Women could select when to have children and were in charge of training them. Traditional clan names were assigned by the matron of the clan. She made sure that no two living persons had the same name. The matron could assign certain names that had political and religious responsibilities.

The duties of a Mohawk woman included providing the food supply. Women and children worked the fields that provided most of the tribe's food. They planted the seeds, weeded the fields, and harvested the crops. Women were responsible for storing the food and trading any surplus for goods not grown by them. The most important food products were corn, beans, and squash, known as the "Three Sisters" in Iroquois culture. Women also gathered maple sap and cooked it into sugar. They supplemented their families' diets with wild crops like berries and nuts. Men's role in producing food was limited only to clearing the fields and hunting for meat.

Because women were responsible for growing the food, they were considered to own the land. All fields were held jointly by the tribe, but clan matrons assigned specific fields to each woman. The right to the use of a certain field was passed down from a woman to her daughters. Women also owned the houses in which their families lived, along with the household goods and food supplies. Married men and women did not share ownership of property. A man's property was limited to his clothing, tools, and weapons.

When the fields around a village were exhausted and the supplies of wood and wildlife

were limited, the tribe would move its settlement. The men were responsible for the heavy work of building new houses and clearing new fields. The women were responsible for the living arrangements. Each extended family lived in its own longhouse, with rooms separated by sheets of bark.

Politically, women were the ultimate authority. Matrons selected the men who served as chiefs and had the right to remove a chief who did not follow the will of the people. Although women did not speak at councils, they could designate men to speak for them so that their will would be known. Women also kept the ceremonial regalia used by the men. They had the right to ask for a raid on another tribe to obtain captives for torture or adoption by the tribe. Women could also stop raids by refusing to provide food supplies for the men. The ultimate fate of a captive was decided by a clan's women.

Women were responsible for religious ceremonies among the Mohawks. They selected the times for festivals and kept the costumes used for celebrating. They also were members of secret medicine societies that provided medical care.

■ Introduction: Society and Culture in the Age of Accelerating Contact

The disruptions of the early modern world changed the perceptions of the humans living in and through them. Definitions of "art" are generally convoluted and contested, yet for our purposes, we can simply accept that art is a creative expression that generally either supports or contests a prevailing world-

view. Political and economic upheavals had an impact on artistic vision, as did exposure to new intellectual stimuli, such as the art and literature of other lands, the Scientific Revolution, and the migrations of various interpretations of Hinduism, Confucianism, and Christianity, as well as exposure to new forms of architecture,

music, sculpture, pottery, and so forth, from distant lands.

The era's upheavals arguably had the mildest impact on China after the Manchu conquest. The founders of the Qing dynasty had long studied and admired Chinese culture. Conversely, Japan, consolidated by Japanese territorial lords, underwent a transformation in art and poetry during the Tokugawa era as urbanization and advances in print technology made literary works more widely available and more lyrically expressive. Europeans responded to intellectual and geographic expansions with a dazzling explosion of literature and art, but Persian literature entered into a decline after religious fundamentalists limited the range available to artists. Persian gardens and architecture reached new heights, arguably because artists and consumers redirected their emphasis. India achieved exciting heights of creativity from a syncretic blending of Turkic Islamic and indigenous traditions. The Ottomans, settled in Anatolia and in contact with multiple influences, also developed impressive art and architecture.

Europe itself underwent an explosion of artistic achievement. Humanism reshaped all aspects of European artistic expression. Baroque symphonies and operas remain exciting and fresh, as do late Renaissance paintings and sculptures. Literature from the pens of social commentators such as Voltaire, Jonathan Swift, and Alexander Pope (to name but a few among hundreds) was vital, sometimes with a biting, shocking wit (as in Swift's satirical suggestion, in "A Modest Proposal," that the Irish sell their babies for sweet, tender meat). Europeans, like societies everywhere, peered at themselves from a new perspective after launching suddenly into an international arena, and as they prepared their bid for international dominance.

—Carolyn Neel

Literature in East Asia

Even though Asia's literary traditions predate those of Europe and the Judeo-Christian world, the literature did not remain in a static state. The drastic political upheavals that occurred in the early modern era in both China and Japan caused a shift in their literature that saw both revival

and innovation. In China the rise of the Ming dynasty in 1368 led to the revival of Chinese literature, which gradually moved toward cultural convention, particularly the "eight-legged essay" genre that was used in grading candidates in the famous civil service examinations. In Japan a new poetic form, *renga*, in which multiple authors participated in literary creation, emerged in the fifteenth century, although the traditional *tanka* genre endured throughout the era.

China possesses one of the greatest literary traditions in the world, and the roots of its literature stretch back some 3,500 years. Throughout this long history, Chinese literature experienced its ups and downs. Under the Ming dynasty, it was dominated by the southern literary traditions and a tendency to establish cultural orthodoxy, which eventually resulted in the development of the eight-legged essay style used to test candidates in competitive literary examinations. The Ming era poets produced a vast amount of poetry, although most of it imitated past masters. The leading voices of the era, as represented by the Qing-Han school, even declared that post-Han (206 BCE–220 CE) era writings were not even worth reading. Yet such sentiments were challenged occasionally, and one of the first voices of protest came from the three Yuan brothers. Yuan Hung-Tao (1568–1610), probably the greatest of the Yuan brothers, argued that poetry should evolve with each age and should convey strong emotions and personal experience. His contemporary playwright Tu Long (1542–1605) also eschewed the formalism of the past and sought a more emotive expression. Two other masters, Chung Hsing and Tan Yüan-chun, tried to break the traditional mold of writing by exploring the possibilities of writing intelligibly without observing Chinese grammatical usages. This period also saw the revival of southern dramatic traditions that employed frequent changes of rhymes and singing as well as plots taken from contemporary life. Chinese prose fiction was revitalized as well. Among numerous works produced in this era, two are particularly important. One, Wu Cheng-en's *Journey to the West*, was an imaginary account of the pilgrimage of the Chinese monk to India, a traditional subject presented in a new and lively manner and, most importantly,

in vernacular language. The second novel, titled *The Plum in the Golden Vase* and also written in vernacular, provided a fascinating yet lurid account of the life of the rogue Ching Hsi-men. Its publication caused a major outcry from the Chinese authorities, who banned the novel and had its first edition, printed in 1610, destroyed.

In 1644 the Ming dynasty was overthrown by the Qing, but this political tumult did not disrupt the development of major trends in Chinese literature. In prose, Chin Jen-jui style remained the common essay form, while most poets imitated the southern Tang style of writing. The Manchu poet Nalan Hsing-te (Nara Singde), one of the best poets of seventeenth-century China, was outstanding. Pu Sung-ling produced a delightful collection, written in classical language (*ku-wen*), of over 400 stories featuring eerie and supernatural events and characters. His other major work was *A Marriage to Awaken the World*, one of the longest novels in any language and produced by the author in vernacular. Pu Sung-ling was, however, soon outshone by other writers. Wu Ching-tzu created *Julin wai-shih* (*The Scholars*, ca. 1750), one of the masterpieces of the eighteenth century, soon joined by another great work, *Dream of the Red Chamber*, a tragic story of the fall of a great family.

Japan already had a long and rich literary tradition by the late fourteenth century. Its poetry was dominated by the *waka* genre that took a variety of forms, most notable of them being *tanka* ("short poem") and *choka* ("long poem"). Yet the fifteenth century saw a gradual replacement of the classic *tanka* by a poetic form that was based on multiple authorship. Known as the *renga* ("linked verse"), it usually featured the *tanka* written by two (or more) people, with one author composing opening lines of a *tanka* and his collaborators completing it. The *renga* genre became quite popular in Japan and later developed rigid rules of composition that, in effect, gradually dampened its freshness. This period also saw the flourishing of short stories that incorporated folk tales and myths as well as historical traditions from the previous eras. A majority of these stories were written anonymously, but scholars suggest that their authors probably were Buddhist monks or court officials. Of great literary value, however, are the Noh dramas, musical

poetic performances in which masked characters performed plays that featured both philosophical and humorous elements. The height of the Noh dramas was reached with Kan'ami and his son Zeami in the mid-fifteenth century, but the genre, with its magnificent poetry and subtle structure, remained vibrant and popular throughout the Muromachi and Tokugawa eras.

The late fifteenth century saw Japan descending into chaos and the anarchy of factional wars that lasted for decades and affected the development of Japanese literature. Yet amity and political unity were restored by the Tokugawas in the early seventeenth century, and Japanese literature thrived once more. Although the Japanese had the printing technology for centuries prior, it was largely limited to the production of religious texts, while literary classics remained in handwritten manuscript forms that highlighted the Japanese art of calligraphy. This changed in the seventeenth century when the introduction of a printing press with movable type (which was actually first brought to Japan following the disastrous invasion of Korea in the 1590s) led to the rise of popular literature as many classical works and eventually works of lesser literary value were produced in print.

The Tokugawa era saw many transformations in Japanese poetry, where the dominance of the *tanka* genre was challenged by the new writers known as *kokugakusha* ("scholars of national learning") who sought to refocus Japanese literature away from Chinese, Confucian, and Buddhist subjects and toward more peculiarly Japanese themes. In this respect, one of the most important literary developments was the emergence of the *haiku*, a new poetic genre that utilized a rather brief form (some 17 syllables arranged in lines of 5-7-5 syllables) to capture moments, sentiments, or images rather than ponder on some lofty ideals. The *haiku* developed from the *renga* poems, whose opening verse of three lines usually contained discussion of landscape, time, or season. Another important literary innovation was the rise of *haikai no renga* (humorous *renga*) that sought to contest the stale set forms of the *renga* and embraced more humorous and vulgar language. Thus, the Danrin school of *haikai no renga* poets preferred impromptu composition that was more appealing

to the fast-paced lifestyle of the *ukiyo* (“floating world”) that developed in the licensed red-light districts of major Japanese cities during the Tokugawa era. In fact, this emphasis on the rapid nature of composition led to the development of a rather peculiar competition, *yakazu* (arrow counting), of one-man composition of extended verses. The first 24-hour competition took place in 1677, with one poet producing 1,600 verses. Yet his prolific output was dwarfed by one of the greatest poets of this genre, Ihara Saikaku (d. 1693), who wrote a 4,000-verse sequence in 1680 and a staggering 23,500 verses in a single day in 1684; all but the very last verses were recorded and published.

The credit for turning haiku into a literary art of the highest quality belongs to Matsuo Basho (d. 1694), the most famous haiku poet of the Tokugawa period in Japan. A master of concise and clear haiku, he emphasized the need for a haiku to reflect real environments and emotions. His verses reflected his rejection of urban life and prolonged travels throughout the country. His *Oku no hosomichi* (*The Narrow Road through the Deep North*, 1694) is usually acknowledged as the most popular and admired work of Tokugawa literature.

The Tokugawa era prose, known as *kanazoshi* (“kana books”) was rather multifaceted and embraced both works of fiction and non-fiction of a wide variety of themes and topics. The spread of printing technology allowed for cheap production of books and a considerable increase in the reading audience. One of the most important writers was Saikaku (discussed above), whose novel *The Life of an Amorous Man* (1682), and *Five Women Who Loved Love* (1686), proved to be highly influential in Japanese literature. The former is a rather licentious work of fiction that focused on the *ukiyo* lifestyle and turned its hero, Yonosuke, into one of the symbolic figures of the era. The latter, however, concentrated on the experiences of common women from the merchants class, the first time that such a “lowly” theme was given a literary treatment. Like Saikaku, Chikamatsu Monzaemon (d. 1725) also chose to write on experiences of ordinary people, particularly the desperate lives of women driven to prostitution.

Literature in Europe and West Asia

Literary practices experienced major transformation throughout the world between the fifteenth and eighteenth centuries. In Europe, Renaissance humanism, the skepticism of the Scientific Revolution, and the rationalism of the Enlightenment all left their marks on the literary legacy. Even though the Islamic Golden Age had already passed by 1500, the Safavid dynasty provided the Islamic world with a new type of literature, one that was more influenced by religion, thereby reviving the literature of western Asia and providing a new forum for religious expression.

One of the most vibrant literary traditions, Iranian literature experienced a major transformation in the sixteenth century. In 1501 the new Safavid dynasty came to power in Iran, dominating it for the next 220 years. The Safavids, devout followers of Shiite Islam, spread Shia creed to the various corners of Iran, affecting Iranian literary traditions. Increasingly Iranian writers and poets devoted their time to religious topics, and the lives and martyrdom of the Shiite imams started to play a focal point in their narratives. Such emphasis on religious use of literature produced the *ta'ziyyah* (“consolation”) writings, the only form of Iranian drama prior to modern times that emphasized religious mourning. The Iranian poetry was dominated by the so-called harmony of images principle that required poets to use in their rhymes only images that belonged to harmonious spheres. Yet one of the greatest poets of the Safavid era, Šā'ib of Tabrīz, broke with this tradition, and his *ghazals* (a poetic form consisting of rhyming couplets and a refrain) introduced Indian artistic flourishes to

Iran. The decline of Safavid power in the late seventeenth and early eighteenth centuries caused an exodus of many literary authors to India, where they enjoyed the patronage of the Mughal rulers.

In Europe, the era of the Renaissance produced a flurry of literary works of wide variety. The introduction of the printing press, credited to Johannes Gutenberg but in use in China for centuries before, only contributed to this process, as it greatly facilitated the production and distribution of written literary works. The number of literary publications in circulation rapidly increased in Europe, starting with first printing a version of the Bible in 1455. The Gutenberg Bible, as it became known, used the Latin Vulgate text in use by the Catholic Church. However, by 1611 after a major scholarly undertaking on the orders of King James I of England, the famous King James Version was finalized and printed. At the same time, published editions of the Bible included the 1516 translation by the Dutch theologian Desiderius Erasmus of Rotterdam; Martin Luther's German translation, which was instrumental in shaping the modern German language; and John Eliot's 1663 Algonquin translation, which played an important role in spreading Christianity and written literary tradition among the Native Americans in North America. At the same time, John Calvin's *Institutes of the Christian Religion* (1536) greatly contributed to the spread of Protestant beliefs in Europe.

Yet Renaissance scholars were not limited to Bible translations. This period also saw a proliferation of pamphlets and tracts, a considerable increase in the translating and publishing of contemporary European authors, as opposed to the classical and medieval works and the appearance of works of moral and philosophical reflection. Sir Thomas More's *Utopia* (1516) dreamt of a "perfect society" where religious tolerance is the norm and women enjoy certain equality with men. Erasmus of Rotterdam had written *The Praise of Folly* (1509), a satire of the corrupt practices of the Roman Catholic Church that, contrary to its author's wishes, soon became part of the Protestant Reformation. The year 1543 saw the publication of Andreas Vesalius's *On the Fabric of the Human Body*, which completely changed understanding of human

anatomy, as well as of Nicolaus Copernicus's *On the Revolution of the Heavenly Spheres* that ushered in the era of the Scientific Revolution. In 1597 Francis Bacon's *Essays* introduced readers to a wide range of philosophical issues.

The popularity of vernacular languages in Europe also greatly increased in this period. In eastern Europe, Cretan literature experienced a revival as it merged vernacular Greek with Latin and Italian, best expressed in Vincenzo Cornaro's *Erotokritos*. In Italy, Niccolò Machiavelli's *The Prince* (1513) provided a sweeping textbook on diplomacy and political machinations, firmly cementing its author's reputation as one of the premier political theorists. Baltissare Castiglione's *The Book of the Courtier* (1528) emerged as one of the most important books of the Renaissance, as it set a new ideal of a well-rounded man skilled not only in war but also in the humanities and fine arts.

In England, the anonymously written *A Gest of Robyn Hode* (ca. 1475) gathered numerous traditions about the English bandit hero and weaved them into one story that fascinated numerous generations. Thomas Malory's *Le Morte d'Arthur* (1485) played a major role in popularizing the Arthurian legend, as it compiled French and English legends about King Arthur and his supporting characters, including Lancelot (and his romance with Guinevere), the Knights of the Round Table, and the quest for the Holy Grail. The works of William Shakespeare became quite well known in the poet's lifetime and in later centuries had a profound effect on Western literature. But Shakespeare's work has been shaped by many other artists. Among his close friends we find the satirist Ben Jonson; the poet Edmund Spenser, famous for his *Faerie Queene*; the dramatist Christopher Marlowe, whose *Tragical History of Dr. Faustus* (1603) was the first dramatic adaptation of the Faust legend; and Thomas North, whose translation of Plutarch's *Parallel Lives* includes many motives and themes that influenced Shakespeare's work. They were followed by Jonathan Swift, the author of one of the greatest English-language satires, *Gulliver's Travels*, and Daniel Defoe, whose *Robinson Crusoe*, a tale of a shipwreck on a deserted island, interests readers to the present day, while Moll Flanders vividly portrayed the dark underbelly of English

society. John Milton's epic poem *Paradise Lost* (1667) inadvertently cast Satan as the passionate protagonist in a struggle against a tyrannical god. In Spain, Miguel Cervantes composed one of the great literary pieces of all time, *Don Quixote*, whose influence on the Spanish language and literature is hard to measure. In France, Molière, Jean Racine, and Pierre Corneille laid the foundations for Western traditions of comedy and tragedy, bringing unmatched mastery to the stage. Francois Rabelais wrote a phantasmagorical series of novels, *The Life of Gargantua and of Pantagruel*, that entertained readers with their extravagant but crude humor and satire.

The Arts in Early Modern India

India's art is famously neither religious nor sacred. Indians do not neatly divide the universe into mutually exclusive sacred and secular realms. Hindu temples often include nonsacred images. These remind worshippers that life's secular purposes of duty, action, and experience are equal to the religious purpose of salvation.

Yet much Indian art has been produced in the context of religious use. In a Hindu temple, for instance, the same image that might be open to the gaze in an art museum is hidden underneath a mound of garlands, jewelry, outfits, silver and gold foil, ghee, and red paste. Some images lead elaborately choreographed lives. The deity awakens in the morning, bathes, dresses, breakfasts, receives guests, enjoys entertainments, and is put to bed at night. All day the temple bustles with the comings and goings of worshippers. Worshippers hold or touch images during some points in ritual. Worshippers do not just look at an image; the image looks back.

Artists often emphasize eyes, such as the almond-eyed beauties of Mughal and Rajput miniature painting or a deity's huge saucer-shaped eyes. The finishing touch on an image destined

for sacred use is that its eyes are "opened" to waken the deity.

Symbols of royalty include the lion, elephant, horse, bull, and fly whisk. Hindu iconography features creatures that are part human and part animal. Fertility and good luck symbols include the woman and tree motif, an embracing man and woman, and mango trees. Hand gestures convey meanings. The uplifted hand, palm facing forward and fingers slightly bent toward the viewer, is the symbol of benediction. Westerners will also recognize the prayer gesture, which originated here.

Buddhists regard the Bodhi tree as a symbol of enlightenment and the wheel as a representation of the law. Jain iconography features holy men. Many Jain symbols resemble those of Hindu figures: the same folk images inspired both. Elongated arms and legs symbolize Jain figures' supernatural nature. Holy men stand or sit in a lotus position. They never lie prone. Saucy female figures and fertility symbols enliven Jain art. And unlike Hindu art, Jain art possesses no violent images, no bloodthirsty demons.

Indo-Islamic traditions elaborate geometric, floral, and calligraphic motifs. Sculptors did not model the human form. Perhaps the most celebrated achievement of Indo-Islamic art was the development of wonderfully detailed miniature painting.

Mughal emperor Humayun recruited Persian artists for a workshop at his court. Humayun's successor, Emperor Akbar, collected European, Chinese, and Southeast Asian art. He encouraged his artists to develop a highly realistic style of miniature painting. Its subject matter was vast: historical events, city scenes, rural landscapes, portraits, animals, incidents from the lives of saints, and even replicas of European works.

Rajasthan and the Punjab Hills also emerged as important centers of miniature painting. The Rajasthani courts at Mewar, Kishangarh, and Kota developed distinctive styles. Kota's Sheikh Taju, the late-eighteenth-century master of animal portraits, used an almost modern style of swift, fluid brush strokes such as in his famed painting *Tiger Hunt*.

European art influences were most intense in the colonies. In Goa, Indian artists reinterpreted madonnas and saints, softening Baroque

sculpture to suit local taste. British-dominated areas produced a hybrid style termed “Company Art.” Subjects include British depictions of Indian painters at work and Indian paintings of British artists at work! Patrons included Mary, Lady Impey, wife of the first chief justice of Calcutta’s Supreme Court. She commissioned many realistic nature studies by painter Shaikh Zayn al-Din. The Nawab of Arcot, for his part, had Francis Swain Ward (1734–1794) paint portraits for his collection.

In a Persian Garden

Beginning with Islam’s origins in Arabia, Muslims have more often than not inhabited harsh environments. Therefore, a garden with trees, flowers, and running water came to represent for them, paradoxically, both a necessity and a luxury. Fresh water has been, of course, a necessity of life over which countless wars have been fought. City dwellers in such places as Delhi, Agra, and Isfahan needed ponds or gardens with water to cool the air. For nomadic peoples who dwelt in deserts and semiarid regions especially, water cooled the air and sustained life. Moreover, because Muslims are obliged to purify themselves through ritual bathing before prayer, water has been indispensable for the rituals of religious practice. Indeed, the cool, shaded, water-rich garden figured in Islamic thought as a metaphor for Paradise. Thus, formal gardens, with their large open spaces suitable to accommodate public gatherings, ceremonies, and festivities, became one of the most characteristic aspects of the Islamic-built environment

wherever Muslim rulers held sway. Practiced as an art throughout the Islamic world, garden design was especially highly developed in Persia and the Indian subcontinent.

The Muslim garden attained a place of privilege as an artistic expression under Babur, the founder of the Mughal dynasty in India (r. 1526–1530). Babur had been born in Central Asia, where gardens were highly developed, and his conquests carried this aesthetic to the subcontinent. Following his capture of Delhi in 1526, Babur commissioned the construction of the *chahar-bagh* design at sites throughout northern India. The *chahar-bagh* style (literally “four gardens,” meaning a garden divided into quadrants) imported into the Indian landscape gardens divided into four symmetrical parts by canals or walkways.

Humayun (r. 1530–1540 and 1555–1556), a son of Babur, was not able to sustain his father’s empire and in 1544 fled to the court of Shah Tahmasp (r. 1524–1576) of Iran. During his exile, Humayun had an opportunity to study the rich complex of Persian art and architecture, with its Il-Khanid, Timurid, and early Safavid influences. It was no coincidence that following his return to India in 1555, Mughal art displayed pronounced Iranian, or Persian, influences.

Humayun’s Tomb in Delhi, India, was one of the earliest Persian-inspired gardens and buildings constructed by the Mughals in India, and it influenced later gardens and buildings in the region. The Persian influence was due to Emperor Humayun’s interest in Persian culture and his Persian wife, who supervised the construction of the garden and tomb; she also employed a Persian architect. (Lian Chang)

► PERSIAN ARTISTIC INFLUENCES ON EARLY MUGHAL ART

When Humayun was driven from India by Sher Shah, an Afghan chieftain, he found refuge in Tabriz, at the Safavid court of Shah Tahmasp, where some of the finest Islamic artists of the day were working. Tahmasp's court studio, or atelier, produced a number of sumptuously illustrated manuscripts such as the *Shahnama* (*The Book of Kings*), an Iranian epic.

Although the Safavids were a Turcoman tribe, their princes took art lessons, following the example of Iran's earlier Persianized dynasties, such as the Timurids. Tahmasp, a connoisseur and patron of miniature painting, actually practiced the art under Bihzad in Herat and Sultan Muhammad in Tabriz, both renowned painter-artists of their time.

Humayun, who had learned to appreciate Persian art during his stay with Shah Tahmasp, brought back to India two of Iran's leading artists, Abd al-Samad (ca. 1514–1599) and Mir Sayyid Ali (dates unknown). Their influence on Mughal art was profound. Under Emperor Akbar, they directed the imperial atelier, where artists produced numerous manuscripts, all noted for their rich Persian-inspired decoration.

—Kumi S. Martin

The most renowned examples of these influences on Mughal garden architecture are the Tomb of Humayun in Delhi and the Taj Mahal in Agra. Both feature a mausoleum as the central building, surrounded by Persian-style gardens. Their scale is massive, an element inherited from Timurid models.

The Tomb of Humayun, built between 1562 and 1572 of red sandstone and white marble by his son Akbar (r. 1556–1605), became a model for Mughal garden-tomb architecture. The complex featured a spectacular chahar-bagh encompassing a dome-mounted square chamber. Although dedicated to Humayun, the mausoleum served as a family tomb, a use that also became a characteristic feature of Mughal garden-funerary architecture.

Similarly, the Taj Mahal, built between 1632 and 1647 by Shah Jahan (r. 1628–1658), was located at the northern end of a chahar-bagh,

which measured approximately 333 yards by 600 yards (308 meters by 554 meters). The Taj Mahal is a monument that commemorates both deep faith and romantic love. Dedicated to Shah Jahan's favorite wife, Mumtaz Mahal, who died in 1631, the site incorporated gleaming white marble and centered the viewer's gaze on a graceful mausoleum that rests on a 22-foot-high (6.7-meter) platform.

The two mausoleums were decorated with both traditional inscriptions from the Quran and elegant Chinese-inspired floral motifs, a form that had developed in Persia, especially during the Timurid era.

The Three Perfections (Sanjue)

One of the most distinctive art forms of medieval China is known as the Three Perfections, or *sanjue*. This art involves a distinct integration of art that combines text and image. At the start of the eleventh century at the height of the Song dynasty (960–1279 CE), it became fashionable among a group of leading Chinese scholars, poets, and artists to seek equal perfection in three areas of their work: poetry, painting, and calligraphy. These skills combined the work of writing brilliant poetry, painting a beautiful scene, and inscribing the poem using excellent Chinese characters. The Chinese literary elite by the start of the Ming dynasty (1368–1644) combined these three skills—painting, poetry, and calligraphy—into a unique art form known as the Three Perfections. They evolved a distinctive aesthetic standard of art involving painting that incorporated poetic inscriptions executed on the work itself using calligraphic styles that were designed to correspond to the aesthetic and intellectual

contents of the painting itself. This highly skilled combination of the three arts over time had a deeply profound influence not only on later Chinese painting but on poetry as well.

Chinese painting traditionally incorporates calligraphy directly on the picture itself. Oftentimes when artists have finished with their painting, they will add an inscription of some sort. The simplest form of this art is when the artists inscribe their names followed by their seal or seals. They may add a date, some reference about the person for whom the picture was painted, or even a note on the occasion or style in which they have chosen to paint. A more complex form of this art occurs when the artist includes a poem or some brief prose that can explore virtually any topic from literature or poetry to metaphysics or philosophy. The ideal of artistic achievement in China is to reach near perfection in all three of the creative processes of poetry, painting, and calligraphy.

The exact origins of the Three Perfections concept is lost in time, but there is a famous story in which the eighth-century Chinese poet, painter, and calligrapher Zheng Qian (d. 764) presented the emperor with an example of his work. The emperor was so impressed with the work that he inscribed the words “*Zheng Qian sanjue*” (*Zheng Qian’s Three Perfections*). The result was that these three art forms—painting, poetry, and calligraphy—became connected and were very highly valued in the visual arts.

One of the most honored avocations of cultivated gentlemen during the Song, Yuan, and Ming periods was painting. During these years the life of a scholar-gentleman, living in the quiet retreat in the garden of his grandiose mansion, could become a poet, painter, and calligrapher or, failing that, a great patron of the arts who collected the works of others. The work of many of these gentlemen was highly prized and respected, and many of the Ming emperors patronized artists. Indeed, the Xuande Emperor, who ruled from 1426 to 1435, was a talented artist in his own right, especially famous for his painting of a variety of animals.

Today scholars have a list of over 1,000 cultivated scholars who became remarkable artists. The amateur ideal of these scholar-gentlemen-artists found expression in the work of Dong

Qichang (Tung Ch’i-ch’ang, 1555–1636), one of the great Chinese painters, scholars, calligraphers, and art theorists of the Ming dynasty. Dong wrote that painting together with poetry and calligraphy was in fact the highest expression of the human spirit. He is famous for his advocacy of approaching painting as though it were calligraphy. Dong epitomized the Three Perfections concept and influenced Chinese art in later periods by rejecting realism in painting and instead advocating a subjective style based on the work of fourteenth-century masters. Dong believed that painting should avoid purely imitative representation and be approached like calligraphy.

Throughout Chinese history scholars have discussed the aesthetics of calligraphy and painting, often noting that the processes of painting and calligraphy are inseparably linked together. The poem reflects the scenery in the picture, the picture forms a backdrop for the poem, and the calligraphy adds to the beauty of the art. It was said that painting could also be called silent poetry (*wusheng shi*), as a painter supposedly wrote out his feelings in silent words. Thus, the appreciation of painting reached its highest fulfillment in the Three Perfections.

Haikai and Kabuki

Japanese culture of the fifteenth and sixteenth centuries was dominated by samurai and powerful local warlords preoccupied with territorial defense, castle building, and pastimes extending from the tea ceremony to verse linking. In the wake of the Battle of Sekigahara of 1600, the Tokugawa clan established itself as the authority of the land and brought a sense of political and economic stability that would last for the next two and a half centuries. This period of great peace allowed the three principal cities of

➤ HAIKU—THE POWER OF SUGGESTION

shizukasa ya
iwa ni shimiiru
semi no koe

stillness—
sinking deep into the rocks
cries of the cicada

The prose introduction to this poem tells us that the author, Matsuo Basho (1644–1694), a pioneer of haikai composition, was visiting a temple in Yamagata named Ryushakuji, known for its tranquility. Everything about the temple reminded him of its age: its remote location, the surrounding boulders overgrown with moss, and the trees. When he reached the temple after a steep climb, he found that the buildings were all closed. This location provides the backdrop for Basho's verse, which develops the sense of silence that enveloped the traveler's destination. Note the characteristic juxtaposition of silence and sound in the poem: the silence referred to in the first line is enhanced by the sound of the cicadas mentioned in the third. A second characteristic is the combination of the momentary and the eternal (*fueki ryuko*). The on-again, off-again trill of the cicadas suggests a kind of sonic cascade that highlights the seemingly unchanging quality of silence for which the temple was so well known. Deliberately ambiguous, Basho suggests the scene using specific details, leaving the reader to appreciate the overtones created by imagining both the sights and sounds.

Kyoto, Osaka, and Edo to flourish, and by 1750 Edo (present-day Tokyo), which had witnessed a dramatic population increase, became the cultural capital of the country. The rapid rise in urban population and the developing merchant-centered economy helped to support a number of popular pastimes, such as *haikai* and *kabuki*.

The composition of poetry had always been a highly social yet primarily elite activity. Like its close relative, linked verse, haikai composition was primarily an exercise in linking. The first verse, called the *hokku*, set out in the first 17 syllables the time, place, and poetic atmosphere for subsequent verses to develop. The responsibility for this important first verse was usually given to the most senior poet present, who would be most apt to start the session on an appropriate note. But poets were more likely to reveal their wit, cleverness, or sensitivity in the link verses that followed, as they surprised by recasting an ambiguous image or amused by playing with words.

Modern readers may naturally associate haikai with the concise and witty independent verses known as haiku, but this more familiar term and form of versification was coined and created by Masaoka Shiki (1867–1902) in the Meiji (1868–1912) period in reaction to what he considered to be the unnecessarily social aspects of haikai and in order to promote the notion of sketching derived from Western-style painting. Haiku in its modern form has become popular around the world today for its economy of language, its appreciation of the natural world, and its juxtaposition of unusual images.

The “hai” of haikai denotes vulgar, coarse, or humorous material and refers to the use of words in poems that fall outside the strictly maintained codes of composition used in the more serious poetry (*waka*) or linked verse (*renga*) traditions. Humorous poems had been preserved in poetry collections as early as the tenth century, and although collections from the beginning of the sixteenth century were devoted exclusively to such humorous fare, the literati considered the composition of haikai to be more of a pastime, a whimsical break from more serious poetic pursuits.

It was in the Tokugawa period that haikai was transformed from a vulgar art into a serious art form on par with *renga*. Early pioneers exploited its potential for word play, and a new range of hitherto disallowed associations, but it was Matsuo Basho (1644–1694) who brought haikai to a new level of artistic maturity. His travelogues, like *The Narrow Road to Oku* (1689),

combined prose introductions with poems using traditional linking principles from the world of linked verse.

Like haikai verse, the kabuki theater has popular roots. Kabuki was one of the art forms of the urban residents of the big-three cities. Despite its humble origins in the early seventeenth century, kabuki theater rose rapidly to become a staple of urban life in Tokugawa Japan.

The word “kabuki” derives from words used to describe unusual, sometimes bizarre, or even cutting-edge artistic activity. Kabuki’s origins date to 1603, when a former shrine maiden named Okuni began performing with other female actors in a dry riverbed in Kyoto. The wildly popular spectacles were often salacious both in content and in manner of performance, and the women performing were often also prostitutes. Dismayed by the public disturbances that these performances created, government authorities banned women’s kabuki in 1623, only to find that the young men who replaced them were just as popular and capable of causing similar disturbances. Young men were then banned from the stage in 1652, to be replaced exclusively by mature men. The tradition of male actors performing as women (known as *onnagata*) is one of the legacies of banning women from the stage.

Government officials were never comfortable with the moral danger posed by the theater, but in spite of the watchful governmental eye, kabuki was flourishing as an art form by the Genroku period (1688–1704). In the print culture of the day, actors rivaled geisha as the most popular subject for colorful woodblock print illustrations that were widely distributed.

The kabuki repertory today continues to draw on famous legends, episodes of cunning bravery from classical literature, stories of lovers cursed by being from different classes, and other vignettes of both the high class and the commoner, grounded in the urban life of the Tokugawa period. Spectators still marvel at the bustling activity on stage and the eye-catching costumes and makeup, and they still roar with applause when actors strike a familiar pose and pause, deliberately, for dramatic effect.

Mughal Aesthetics

Over the long period of Mughal rule (ca. 1526–1857), Mughal architecture and art revealed an evolving artistic aesthetic. The term “aesthetic” refers to a prevailing philosophy of “the beautiful” that underpins taste and determines the style and range of artistic productions. While the Mughal aesthetic evolved over time, the purpose and function of this art and architecture remained relatively constant. The common will to commission and create monuments with distinct purposes—whether to promote religious ritual or to represent the government, embodying its power, dignity, and splendor—is recognizable in the art. Nevertheless, Mughal architecture changed and evolved; indeed, it was constantly renewing shapes and decorative details, enriched by the combining of elements inherited from different traditions, particularly as the Mughal's Persian heritage blended with Indian culture and tastes over the centuries. The resulting blend of once-distinct cultures and forms is an example of syncretism.

Emperor Akbar's Mughal pavilion known as Diwan-i-Khas at Fatehpur Sikri, India. (Dennis Richardson)

In Mughal artistic production there is a clear preliminary line of demarcation of style, approximately identifiable with the midpoint of the sixteenth century. The previous need felt by the sovereigns to extend and fortify the new kingdom did not allow them to dedicate and concentrate efforts in the definition of an aesthetic taste. Current research suggests a general division, usually unanimously recognized and accepted, of two main phases of Mughal architectural and artistic production, each marked by a different general aesthetic. The first period is identified with Akbar (1556–1605), the third ruler of the Mughal empire and an influential patron of cultural and artistic development. Akbar founded a royal atelier and became the first great patron of the empire. Akbar's patronage culminated in the construction of the city of Fatehpur Sikri (1571–1585). This new fortified residence for the court embodied all the features that characterized this period, constituting a perfect example of Akbar's taste. The predominance of red sandstone and the shapes' affinity with wood from a construction point of view aided its deep integration with indigenous elements that came from Hindu and Jain architecture and from the dominant influence of the Indian region of Gujarat. This structure offered a new syncretism (or fusion of distinct styles) evident in the truss supported by pillars, heavy brackets, capitals, and the symmetrical frameworks that enriched the Timurid tradition inherited from Central Asia and accompanied the structural rhythm. The building combined rationality with vigor, solidity, and power, balancing and harmonizing its masses. In painting, Akbar created a studio in his court and promoted the Persian miniature painting that utilized Indian, Hindu, and even European elements.

The second phase in Mughal aesthetics, begun during the rule of Jahangir (1605–1627), became pronounced with the accession to the throne of Shah Jahan (1628–1657). The new architecture showed a preference for white marble over red sandstone, which required a change in construction techniques and even of the decorative patterns. The decoration schemes became lighter and more delicate, but at the same time these were embellished with the introduction of semiprecious stones in exquisite inlaid work;

the new style perfectly expressed a new hierarchical conception in which specific decorative motifs were used to emphasize salient structural elements, creating a return to an equilibrium and an elegance closer to the Western conception. Styles of painting also became refined: realistic portraits of courtly scenes were the favorite subjects of painters, who emerged now as individual talented personalities. Even the reversion to Islamic religious orthodoxy helped consolidate the new artistic purposes. This transition culminated undoubtedly in the Taj Mahal (1632–1647), whose elegance and refinement is the highest result of Shah Jahan's strenuous insistence on artistic and architectural perfection. The Taj Mahal represents the perfect incarnation of the imperial splendor and magnificence of the Islamic court.

From the beginning of their empire, the Mughals' art was strongly characterized by very complicated cultural and artistic backgrounds. Many elements contributed to the formation of these aesthetic canons and, in time, evolved with the manifestation of the power. A primary role in the formation of the new taste for beauty was certainly held by the whole artistic production of the many previous Islamic dynasties that reigned mainly in northern India. They perhaps provided the first models, but these antecedents could not entirely define the new style that had deeply drawn from the Islamic world, from India's background, and from Islamic regional styles.

These early factors were soon transformed by the personal tastes of the many emperors who succeeded to the Mughal throne. Their interest in construction and patronage, often associated with their charismatic personalities and active supervision of artistic production, was able to impress their own personalities on each monument. The typology of the buildings, the plan, and the choice of materials, decorative elements, and schemes were all aspects that contributed to the formation of aesthetic canons.

Nevertheless, a crucial factor enabling the Mughals to reach such a high level in artistic and architectural production was the dependence on local workers and craftsmen. Unconsciously but inevitably, in the realization even of new shapes and in construction techniques, they constantly transmitted and transposed to the

SHAH JAHAN AND THE TAJ MAHAL

Commissioned by the Mughal emperor Shah Jahan (r. 1628–1657) to commemorate his favorite wife, Arjumand Banu Begum (also known as Mumtaz Mahal), construction of the Taj Mahal began at Agra in 1632 and was completed, according to historical records, in 1647. The mausoleum, perhaps the most beautiful and famous monument in the world, perfectly epitomizes Mughal aesthetics and represents the syncretism of the Mughals.

The mausoleum is the heart of an extensive architectural complex along the Yamun River. Carefully planned, the Taj Mahal overlooks an enormous *chaharbagh*, or garden complex, and includes many different structures: a residential court for the tomb attendants, a bazaar, subsidiary tombs, and a mosque. The mausoleum was built in white marble, carved and decorated with refined inlaid stones that depict images of flowers. The structure perfectly assimilated Islamic and Persian motifs as well as Hindu elements as part of its larger synthesis.

Although art historians for many years studied the Taj Mahal as a poignant and romantic symbol of eternal love, it reveals an unexpectedly complex cosmological conception. According to a more recent interpretation, the general plan, the garden, the decorative scheme, and the accurate choice of the inscriptions—Quranic verses relating to the Day of Judgment—all clearly refer to the Garden of Eden. In this interpretation, the Taj Mahal may represent the Throne of God and implies Shah Jahan's celebration of himself as a semidivine ruler.

—Sara Mondini

Mughal monuments the traditional aesthetic canons unique to indigenous Hindu or Jain architecture. Thus, this syncretism, the confluence of all these elements, was the basis for the remarkable aesthetic results reached in this period perfectly expressed in the most famous of Mughal monuments, the Taj Mahal.

Ottoman Religious Architecture

During the long history of the Ottoman empire, architecture proved to be one of the most dynamic and major fields of Ottoman cultural activity. It developed in a unique environment whereby the Byzantine and eastern European traditions merged with Seljuk, Iranian, and central Asian building techniques and customs to produce a distinctly Ottoman character. The architectural legacy of the Ottoman empire is remarkably multifaceted and includes military buildings (fortresses, barracks, arsenals), religious buildings (mosques, minarets), schools (madrasas, primary schools [mektebs]), commercial buildings (caravansaries, bazaars [bedestens], arastas [street of shops whose income was devoted to a charitable endowment]), bathhouses (hammams), public fountains (sebils), bridges, and graves. The Ottomans' architectural policy was set and controlled by a chief architect who was charged with controlling major projects throughout the empire. This centralized system of construction meant that the Ottoman architectural style was relatively uniform across the vast imperial territory that stretched from Tunis and Libya to Hungary and Iraq. An important and unique element of the Ottoman architecture is the fact that many buildings—fountains, hospitals, schools, caravansaries—were designed and built to provide free service to the people. These vast and prolific architectural pursuits were funded by revenue assignments (*dirlik*, *temlik*) and tax farms (*mukata'a*, *malikane*) as well as donations from the sultan, his relatives, and prominent officials. Viziers and provincial governors often patronized various

architects and channeled a considerable share of their revenues into architectural projects, which in turn were supervised by chief architects.

Religious architecture represented the most vibrant and flexible element in Ottoman architecture. This is partly due to the very nature of Islam, which lacks sacraments and formal ceremonies and therefore limited ritual requirements for a structure. In addition, the early Ottomans lacked an architectural tradition and were open to adopting the traditions of more sophisticated cultures. The most ubiquitous example of the Ottoman religious architecture is a domed mosque, surrounded by one or more minarets and other buildings and forming a complex (*kulliye*) that incorporated religious, educational, and other facilities. The early mosques were usually medium-sized single-domed structures that often included hospices, styles that were largely influenced by the Byzantines. As the imperial power grew, the mosques experienced a dramatic transformation, and their size and design increased and became more sophisticated. The Ottomans gradually mastered the technique of building vast inner spaces with seemingly weightless yet expansive domes. In later years, the mosque interior was covered with intricately designed Iznik ceramic tiles; due to Islamic prohibition on figural decoration, Ottoman artists focused on abstract (floral, geometric, epigraphic) ornaments by experimenting with numerous textures and motifs. Among the early religious structures, the most notable are the mosque of Orhan Bey (erected in the early fourteenth century in Bursa) and the Ulu Cami (the Great Mosque, built by Sultan Bayezid I in 1396–1399 in Bursa), which eventually included a large commercial complex. The Uch Sherefeli Mosque, built by Sultan Murad II in 1438–1447 in Edirne, is an important benchmark in the development of Ottoman architecture. It is a structure with a 72-foot (22-meter)-diameter dome on a hexagonal based flanked on either side by smaller domes and unusual three-balconied minarets.

Following the conquest of Constantinople in 1453, a new period of development began in Ottoman architecture. Ottoman architects were inspired by the Hagia Sophia, the famous sixth-century Byzantine church, and sought to match (and exceed) its beauty and scale. Immediately

after the conquest, Sultan Mehmed II the Fatih (Conqueror) embarked on reviving and reconstructing the former Byzantine capital, often-times using the Byzantine buildings as the basis for new structures. Under Mehmed's watchful planning and guidance, the Ottomans completed several grand projects. One of them was the Fatih Mosque, built on the site of the Byzantine Church of the Holy Apostles and incorporating a vast complex of eight colleges as well as a library, hospital, hospice, caravanserai, market, bath, and primary school and a public kitchen for the poor. The Fatih Mosque, with its combination of a dome with a number of semidomes, set a model for many subsequent mosques. The Ottomans also built the famous Seven Towers (Yedikule) fort, the Eyup complex of bazaars, the Imperial Cannon Foundry (Tophane), and the renowned Topkapi Palace that features three consecutive inner courtyards and dozens of administrative and court structures.

The classical age of Ottoman architecture was during its height of leadership in the sixteenth century under sultans Selim I and Suleyman the Magnificent. Yet Koca Mimar Sinan Ağ (1489–1588), known as Sinan, reigned supreme. As the chief Ottoman architect for nearly 50 years (1539–1588), he supervised the construction of every major building in the empire and is credited with at least 334 structures erected during his lifetime. Sinan built some of the finest examples of Ottoman architecture, including the Suleymaniye Mosque and Atik Valide Sultan mosque in Istanbul and the Selimiye Mosque in Edirne. For Sinan, the Suleymaniye Mosque was an architectural counterpoint to the Hagia Sophia. The mosque is preceded by a vast courtyard with a colonnaded peristyle and four tall minarets, while its main structure consists of a vast 173-foot-high and 85-foot-wide (53-meter-high and 26-meter-wide) dome and a series of semidomes billowing out from the main dome. The remarkable height and breadth of these domes, which are dotted with small windows, made the inside of the mosque seem spacious and light as opposed to the dim chambers of the Hagia Sophia. The Selimiye Mosque is sometimes described as the climax of Ottoman architecture, as it features the largest Ottoman central domes (105 feet or 32 meters wide) and

Yeni Camii (New Mosque) in Istanbul. The mosque was started in 1597 by Safiye, mother of Sultan Mehmed III but was not completed until 1663, after Turhan Hatice, mother of Sultan Mehmed IV, had taken up the project. (Anna Kankia)

the tallest minarets (232 feet or 70.7 meters). Besides mosques, Sinan also built a series of aqueducts, which brought much-needed fresh water to the growing city of Istanbul, and numerous bridges throughout the empire, the most famous being the Buyukchekmece bridge near Istanbul, the Sokollu Mehmed Pasha bridge in Visegrad (Bosnia), and the Uzunkopru bridge over the Ergene River.

Sinan died at a very advanced age, and Davud Agha, with whom Sinan collaborated on many projects, was appointed successor to the dead master. While completing Sinan's unfinished projects, Agha also embarked on new ones, including two kiosks in the palace gardens for Sultan Murad III and the famous mosque for Safiye Sultan, mother of Mehmed III. Around 1650, Sultan Ahmed changed the former tradition of appointing the chief architects for life. He dismissed his chief architect and appointed men who excelled not only in arts but also in bureaucratic and military service. The seventeenth century saw the completion of several grand projects, including the renowned Sultan Ahmed Mosque, also known as the Blue Mosque, that incorporates Byzantine elements with traditional Islamic architecture and is considered to be the last great mosque of the classical age. It features a vast complex of a school of law and divinity, a public kitchen, shops, and hospices and is the first mosque to have a royal apartment. The Blue

Mosque served as a model for another major mosque constructed by Turhan Valide Sultan in the late seventeenth century. In the late seventeenth and early eighteenth centuries, Ottoman architecture entered the so-called Tulip period when it was greatly influenced by rococo and Baroque styles from Europe. The Nuryosmaniye Mosque, built in 1749–1755, became the first mosque constructed in the Baroque style, and its complex includes a school, library, kitchen, and public fountains enclosed in an irregular walled-in courtyard.

The Ottoman funerary tradition represents a unique element of Ottoman religious architecture. Mosque complexes often featured the tombs of sultans and their relatives in addition to cemeteries. The simplest and most prevalent form of Ottoman burial was a grave with two vertical stones marking the head and the foot. Men's headstones often incorporated their headgear, which indicated their rank or affiliation, while women's graves usually featured floral motifs. In some cases, modest tombs—often octagonal with a dome—were built for prominent individuals, such as the tomb of Hurrem Sultan (Roxelana), the wife of Suleyman the Magnificent. Another important feature of the Ottoman religious architecture is the presence of bathhouses and public fountains. To maintain personal hygiene for ritual prayers is a religious requirement in Islam, and thus access to bathhouses and fountains was of paramount importance. Therefore, mosque complexes usually incorporated one or more public fountains to allow the faithful to prepare for prayers, while the famed Ottoman bathhouses featured tepidariums, steam sections, and pools.

European Architecture—Palace and Cathedral

While the roots of the Italian Renaissance may lie within the fourteenth century and earlier, it did not fully impact architecture until the late fifteenth and early sixteenth centuries. Reflecting the rebirth of ancient classical taste, architects favored the structural features of the Roman column, with its balance of vertical and horizontal forces. Thus, Filippo Brunelleschi (1377–1446), guided by his intense study of ancient Roman buildings, designed two churches in Florence—San Lorenzo and Santo Spirito—with the early basilica form and classical columns. Moreover, he designed Florence's Santa Maria del Fiore Cathedral dome (the familiar church dome of the city's skyline), innovatively utilizing an octagonal shape for its base. Brunelleschi also holds the distinction as the first architect to delineate the mathematical rules of perspective. Equally inspired by the ancient Roman style was his colleague Leon Battista Alberti (1404–1472), whose use of flat roofs, overhanging cornices, and stress on horizontal lines is representative of Renaissance architecture in Italy. With his San Andrea Church in Mantua, Alberti "Latinized" his architectural vocabulary by harkening back to the ancient brick architecture of late Roman times.

Following this humanist revival, there arose a sixteenth-century period of tremendous artistic experimentation known as Mannerism, aiming for the creation of optical pleasure and intensity through exaggeration and eclecticism. Mannerist architecture enforced movement through rhythmic lines within limited spatial confines, thereby generating greater visual complexity than the classical norm. The career of Andrea Palladio (1508–1580) furnishes a case study of the ways in which Mannerism gradually altered Renaissance ideals. During his lengthy career, Palladio earned many commissions for palaces and churches. Typifying Palladio's early work is the Palazzo Chiericati (1550), its facade employs Doric columns on the bottom stage of the building and Ionic columns above, and on the roof cornice statues appear above each column. More progressive is his Villa Barbaro, built near Treviso in 1557, on which Palladio collaborated with painter Paolo Veronese (1528–1588)

on the Mannerist interior decor encompassing many *trompe l'oeil* (fool-the-eye) effects. These included spaces where human figures were painted life-size to give the illusion of reality. Palladio amplified Mannerist techniques in his Church of San Maggiore (1565) in Venice, just across the canal from St. Mark's Square, as the sanctuary breaks up classical lines in the ceiling cornices and elsewhere. Palladio's artistic pendulum swung fully in the direction of Mannerism with his Palazzo Thiene (1572), on which he collaborated with Bartolomeo Ridolfi (1510–1574) to craft fantastic fireplaces in a grotesque style; the most famous depicts the one-eyed Colossus from Homer's *Odyssey*.

Around the turn of the seventeenth century, Mannerism gave rise to Baroque architecture, which combined the earlier experimentation with curved surfaces, sculpture, richly decorated walls and ceilings, and expansion of horizons. This final characteristic led to the renovation of old buildings and the erection of new buildings in many parts of Europe. Exemplifying renovations was Louis XIV's (1638–1715) Versailles expansion project, which manipulated line and color to create dramatic movement and tension. Desiring to evoke infinity, the Hall of Mirrors, designed by architect Jules Hardouin-Mansart (1646–1708) and painter Charles Le Brun (1619–1690), contains mirrors placed opposite the 17 large windows for reflecting the light and garden outside. The resulting depth and atmosphere are enhanced by the historical ceiling paintings, which portray the king's military victories and exalt the royal family. Outdoors, a feeling of infinite spaciousness was achieved by fountains and reflecting pools, strategically placed to yield reflections of the building facade, the sky, and vegetation. Exemplifying new buildings were the new churches necessitated by the growth of the city of Amsterdam. In 1614 Hendrick de Keyser (1565–1621) designed the Zuiderkerk (South Church), replete with oval-shaped openings and bulbous ornamental shapes. De Keyser's so-called *architectura moderna* continued with his 1620 Westerkerk (West Church), the Reformed temple where the painter Rembrandt (1609–1669) would later be buried. The temple is in the unusual form of a basilica, with arched recesses and oval openings at the gable ends of

Built by Brunelleschi between 1420 and 1428, this Renaissance chapel exhibits symmetry and geometrical unification through circles, semicircles, and rectangles. The tripartite apse represents the three persons comprising the one God. Both doors are cast in pure bronze; the left door is the Door of the Apostles and the right door is the Door of the Martyrs. (Erich Lessing/Art Resource, NY)

two short transepts. Both churches manifested *trompe l'oeil* through colored marbles, precious stones, stucco, and metals.

Baroque ideals came to their fullest architectural expression in eighteenth-century Germany and Austria. A designer of palaces and churches, the German architect Johann Balthasar Neumann (1687–1753) perfected the techniques of illusionism: richness of texture, color, and shape; curvature and other linear irregularities; motion and rhythm; and dramatic depth and perspective. Among his masterpieces is the Würzburg Residenz (built 1720–1744), the palace of the bishops of Würzburg. The collaboration of Neumann and Italian painter Giovanni Battista Tiepolo (1696–1770), the palace's Kaisersaal (emperor's room) featured such ceiling paintings as the *Marriage Ceremony of Barbarossi* coupled with the *trompe l'oeil* depiction of large groups of figures positioned on the balcony above the wedding party and spilling over the ceiling cornice in a lifelike fashion. Within the Brühl Palace, Neumann was asked by the elector of Cologne in 1745 to create a magnificent staircase, where colored stucco marble combines with frescoes and stucco sculpture to form an awe-inspiring composition of Baroque decor. Among Neumann's churches is the Vierzehnheiligen (Fourteen Helper Saints) Pilgrimage Church (1750) near Bamberg, containing a complex system of ribs and domes that produces rhythmic spatial effects. With his trademark stucco decor, in 1752 Neumann completed the Abbey Church at Ottobeuren, begun by Austrian architect Johann Bernhard Fischer von Erlach (1656–1723). Erlach had designed such Viennese buildings as the Library of the Hofburg

Palace (1722), Karlskirche (built 1716–1723), and Schonbrunn Palace (built 1693–1723) as well as the Collegiate Church in Salzburg (built 1696–1707). Arguably the leading representative of Austrian Baroque style was Johann Lukas von Hildebrandt (1668–1745), who drew upon his Italian training to design Vienna's Belvedere Palace (built 1721–1742) and St. Peter's Church (built 1702–1753).

Eighteenth-century France saw the blending of Baroque with the brief Rococo style (1715–1770), which exploited decoration imitative of small rocks, shells, leaves, flowers, scrolls, and tendrils to adorn wall panels and borders. Rococo typically exhibited a light miniature style and pastel colors, as displayed in Paris's Hotel de Soubise (built 1737–1740) and a myriad of French salons.

European Religious Art from Renaissance to Baroque

In the Renaissance and High Renaissance periods, roughly from the mid-fifteenth century to the early sixteenth century, Europe experienced a cultural revolution. The term “Renaissance” means “rebirth,” and the artists of the time were inspired by Classical culture. Religious art, as in the Middle Ages, continued to be popular in the Renaissance period, but artists' techniques and styles changed. Natural beauty and human creativity were seen as reflections of God's power, as religious figures were portrayed more realistically. The art of the Baroque period in the seventeenth and eighteenth centuries added drama, flourish, and emotion to Christian subjects and imagery.

Renaissance painters were inspired by Classical Greek and Roman cultures and their emphasis on realism and the beauty of the human form. Artists began playing with color, light, and perspective to create lifelike figures. Religious subjects were typical, as most of the art was commissioned by patrons and specific churches. But unlike the religious art of the Middle Ages, biblical figures were painted and sculpted with a great deal of three-dimensional detail, and stories appeared in contemporary landscapes and natural settings. Artists, first in the Netherlands and later in Italy, began to mix oil with pigments, which created slow-drying paint and allowed artists to create more detailed paintings. Popular religious subjects included the Annunciation (Mary's visitation by the angel Gabriel, who tells her that she will be the mother of Jesus Christ), the Adoration of the Magi (the Nativity of Jesus and his visitation by the three wise men), the Madonna and Child (the Virgin Mary with the infant Jesus), the baptism of Christ, stories from the Old Testament, the Saints, and pietàs. The term “pietà,” from the Italian word for “pity,” is a painting, sculpture, or drawing depicting the Virgin Mary mourning over and holding the dead body of Jesus.

Religious art during the Renaissance period was rich with Christian symbolism and reflected the world in which the artists lived. Everyday objects were frequently found in artistic portrayals of biblical scenes such as flora and fauna, animals, earth and sky, colors, clothing, objects, and human bodies, and these items symbolize religious concepts. For example, thorns might allude to Christ's crucifixion and death, a dove might symbolize peace and purity, and a lamb could represent Christ himself. Artists like Italian Venetian painter Giovanni Bellini (1430–1516) specialized in detailed landscapes, and many of his paintings portrayed biblical subjects in contemporary Italian settings. Sandro Botticelli (ca. 1444–1510), an important Italian Florentine painter during the Early Renaissance, included members of the House of Medici (a powerful political banking family who were passionate patrons of the arts) in his *Adoration of the Magi*, demonstrating that politics, contemporary figures, and popular issues found their way into the religious art of the period.

➤ MICHELANGELO AND THE CEILING OF THE SISTINE CHAPEL

Michelangelo Buonarroti (1475–1564) began work on the ceiling of the Sistine Chapel, located in Vatican City, Rome, in 1508 at the commission of Pope Julius II. Michelangelo was unhappy about the task, as he considered himself primarily a sculptor and did not want to leave his current work on the pope's tomb. But Michelangelo undertook the work and spent four years painting the nearly 12,000-square-foot (1,115-square-meter) ceiling. The result was over 300 life-size biblical figures and scenes from the Old Testament. The ceiling is not only one of Michelangelo's most famous works but is perhaps one of the most well-known pieces of art in the world.

Michelangelo painted in fresco, a technique in which paint is applied to wet plaster. To reach the ceiling, he built his own special scaffolds and labored through incredibly cramped conditions,

both standing and lying down on the scaffolds to complete the painting. Initially, he was asked to paint the Twelve Apostles, but he had grander plans. Paintings on the ceiling include the ancestors of Jesus, several major and minor prophets, nine scenes from the book of Genesis, and various other figures.

The ceiling demonstrates the remarkable detail, realism, and ideals of the Renaissance period, as the scenes depict the dramatic stories from Genesis and the creation of the world to the last judgment. The hand of God reaching out to Adam in his *Creation of Adam* (ca. 1511) is one of the most well-known and recognizable paintings on the ceiling. Although Michelangelo painted this piece nearly 500 years ago, it continues to be an iconic work.

—Kim Kennedy White

The High Renaissance period, roughly the first two decades of the sixteenth century, produced perhaps the greatest artists of the past 500 years. Leonardo da Vinci (1452–1519) is not only one of the most well-known painters of all time but was also an inventor, sculptor, and architect. He was a master of mathematical perspective, composition, and space. One of his most well-known pieces is the painting *The Last Supper* (1497) that portrays the final days of Jesus with his disciples. Michelangelo Buonarroti (1475–1564) was the most important sculptor of the High Renaissance period who drew the attention of the Catholic Church with his *Pietà*, sculpted in 1500. During his career, he served six popes and is perhaps best known for his sculpture of the Old Testament figure David (1504) and painting the ceiling of the Sistine Chapel (1511–1512). Raphael (1483–1520) was another gifted painter who was commissioned to paint religious subjects on church altarpieces and cabinets and, later, rooms in the Vatican and several papal portraits. He was known for his idealistic and ultrarealistic figures.

Although the High Renaissance was primarily an Italian phenomenon, Northern Europe also produced master artists who later influenced the Renaissance movement. Early

Renaissance painters from the Netherlands, such as Jan van Eyck (ca. 1395–1441), introduced an almost superhuman realism to artwork. Van Eyck's oil paintings on panels and altarpieces brought to life saints and angels of heaven. Another influential artist from Germany, Albrecht Dürer (1471–1528), was renowned for his meticulously detailed engravings and woodcuts, most notably his *Four Horseman of the Apocalypse* series (1498) that depicted the end of the world, as described in Revelation, in fantastic and horrific detail.

In the Baroque period from the late sixteenth century to the early eighteenth century, the arts underwent a dramatic shift from the symbolic imagery of the Renaissance to a more direct and emotionally realistic depiction of religious themes in art. During the Council of Trent (1545–1563), the Roman Catholic Church demanded clear religious meanings in art in order to reach not only the noble people but the illiterate masses as well. Paintings and sculptures in the Baroque style brought the subject matter directly to the viewer through light, color, space, and dramatic flourishes. Some of the most well-known artists include Italian portrait painter Caravaggio (1571–1610), Flemish painter Rubens (1577–1640), and the Netherlands artist

Rembrandt (1606–1669). While Renaissance art demonstrated restrained realism, Baroque art showed exuberant feeling and extravagant style. A major artistic technique that artists used during the Baroque period to bring that energy to life on the canvas was *chiaroscuro*, or the contrast between light and dark. These extreme contrasts brought the grandiose movement, spiritual conviction, and fervent emotion of religious subjects to life.

European Drama—Shakespeare, Marlowe, Lope de Vega, Calderon, Moliere, and Gil Vicente

Between 1440 and 1770 European theater evolved from the religious to the secular, providing the framework for contemporary dramatic structure and practice. Critical events contributing to the Pan-European transformation include the Protestant Reformation, which banned religious drama, and the humanist philosophies of the Italian Renaissance. In becoming increasingly secular, drama became increasingly complex both structurally and thematically, necessitating developments in theater architecture, playwriting, acting technique, and production design.

European theater in 1440 was inseparable from Catholic religious practice. The most prevalent form, Mystery Plays, presented religious teachings through the combination of farce, moralism, and ritual in the depiction of biblical stories. Performed by craft guilds in town centers and in England upon mobile carts, the plays often accompanied religious festivals. Pageant-like and in the vernacular, they featured elaborate sets and costumes, realistic effects, and technological inventions such as the hell mouth. Famous Mystery Plays include England's *York Cycle* and Spain's *Misteri d'Elx*.

Religious drama also included Miracle Plays, depicting the lives of saints, and Morality Plays, teaching Christian values through the personification of abstract figures such as Vice and Virtue, the most famous of which is *Everyman*. The Protestant Reformation banned religious drama due to its strong historical connection with Catholic rituals, resulting in the secularization of drama. Combined with the development of itinerant acting troupes, secularization caused differentiation of national dramatic styles and the birth of modern narrative drama.

The Italian Renaissance featured a resurgence of classical Greek drama and with it construction of theaters based on ancient amphitheaters. In 1545 the architect Sebastiano Serlio published three perspective drawings depicting the Comic, Tragic, and Satyric (or Pastoral) scenes, resulting in painted backdrops that led to the development of the proscenium arch, or the arch at the front of the stage that separates the performers from the audience. In Western theater the proscenium stage became the dominant architectural form, yet the greatest impact of Italian drama came from Renaissance humanist philosophy and the techniques of touring *Commedia dell'Arte* troupes, which would thematically and structurally impact European secular drama.

Elizabethan English drama featured governmental censorship, a patronage and shareholder system, and a ban on actresses. In 1576 James Burbage built the first permanent English theatre, The Theatre, outside of the London city limits due to the anti-theatrical prejudice of city officials, a practice that continued until the Restoration. Theaters utilized the thrust stage that

► COMMEDIA DELL'ARTE

Commedia dell'Arte, a theatrical form employing masked actors and improvisation, emerged in Italy in the mid-sixteenth century. With many elements stemming from Roman Comedy, the plays featured a preestablished plot, most often a romance, upon which the actors improvised. This allowed performances to reference and mock current events, marking the first time that drama actively engaged with contemporary life. The farcical slapstick style emphasized the actor's physicality and consisted of lazzi (rehearsed comic gags) and burle (long improvisational practical jokes).

Except for the innamorati (the young lovers), the actors performed in masks, each unique to a specific character type. These same characters appear throughout Commedia, and each in addition to their mask has a specific physicality. The most famous and influential Commedia characters are the clown figures, the zanni. Often a servant, they control the plot and possess the greatest freedom of improvisation. The zanni included Arlechino, Pierrot, Brighella, and Grattiano, with most plays featuring at least two zanni

figures, one quick-witted and one slow. Additional Commedia figures include Il Capitano, the Spanish soldier who brags of his conquests but is ultimately a coward; Colombina, the saucy maid-servant; and the old man characters of Il Dottore, the doddering pedant, and the avaricious and unintelligent Pantalone, often guardian of the female innamorata.

Traveling Commedia troupes spread the form throughout Europe, and the plays of Shakespeare and his contemporaries provide clear evidence of Commedia's impact. Many of Shakespeare's characters, including Malvolio (Grattiano), Puck (Zanni), and Polonius (Il Dottore), and plots, such as in *Romeo and Juliet*, *Twelfth Night*, and *Two Gentlemen of Verona*, can be directly traced to Commedia. In addition to its literary impact, the introduction of improvisation led to spontaneity and immediacy in performance, two concepts that still influence acting technique. In the twenty-first century, Commedia continues to be developed and performed.

—Kellyn Johnson

protrudes into the audience, a feature unique to English drama at the time.

The stage architecture and lack of painted scenery led to a primarily aural theater. Audiences went to hear a play, causing the linguistic emphasis exhibited by William Shakespeare and his contemporaries Ben Jonson and Christopher Marlowe. Shakespeare, an actor and playwright, has come to define the period for modern audiences. His plays, primarily in verse, present emotionally developed characters in complex plots. He was a shareholder in the King's Men, a royally chartered company, along with Richard Burbage, the period's leading actor. Marlowe, who heavily influenced Shakespeare, implemented the use of blank verse in drama, and his *Doctor Faustus* remains one of the most highly regarded texts in English drama.

Ben Jonson, a highly successful comedic playwright who employed biting satire in plays such as *Volpone*, also wrote the elaborately designed *Court Masques of Inigo Jones*. They featured intricate sets, costumes, and special effects

that furthered theatrical technology and design. These included the introduction of backdrops and wings, or side partitions through which actors could enter, to the English stage, leading to the prominence of the proscenium stage.

Following the Elizabethans, Jacobean playwrights include John Fletcher and Francis Beaumont, who explored extremes of High Tragedy and Low Comedy, and John Webster, who wrote Italian-influenced dark plays of political intrigue. The civil war interrupted theatrical development in England as the Puritans closed the theaters until the Restoration of Charles II in 1660. The diaries of the afficianado Samuel Pepys provide detailed information regarding Restoration theatrical culture and practice, including the French theatrical influence on Charles II in his exile, which led to the introduction of the actress, most famously his mistress Nell Gwynn and Mrs. Betterton, to the London stage.

Restoration Comedy, featuring plots of intrigue and adultery, was the dominant form until the 1680s, when it was replaced by Sentimental

Drama, represented by Colley Cibber and Sir Richard Steele, and Satire, represented by John Gay and Henry Fielding. Other key playwrights of the period include William Congreve, William Wycherley, George Farquhar, and the first professional woman playwright, Aphra Behn. The Licensing Act of 1737 gave Lord Chamberlain absolute power of censorship, reducing the number of new plays, causing performers to gain greater fame and importance, and culminating in the star status of actor David Garrick who introduced the naturalistic style of acting throughout Europe.

Portuguese playwright Gil Vicente provides the link from medieval to Renaissance drama in the Iberian Peninsula. He wrote religious dramas, most famously *Trilogia das Barcas* (*Trilogy of the Ships*), as well as satirical comedies in both Portuguese and Spanish. His work provided a foundation for future Portuguese and Spanish playwrights by inventing the farce. These playwrights included Félix Lope de Vega, who wrote over 1,200 plays. Referred to by his contemporaries as a “monster of nature,” Lope de Vega worked within a strict three-act structure in which the conflict leads toward the development of a more perfect social order. Additional Golden Age playwrights include Tirso de Molina, who wrote the first Don Juan play, and Pedro Calderon de la Barca, who wrote comedies of intrigue, court spectacles, and religious essays. Their plays, which were performed in impermanent open-air theaters called corrales, were purchased by companies that hired performers, including actresses, on salary.

In his 1637 play *Le Cid*, Pierre Corneille introduced Spanish tropes to French drama, which primarily utilized a classical model based upon Aristotelian unities, featuring a rigid divide between comedy and tragedy. Jean Racine was the master of tragedy in the period, while Moliere, an actor and a director, designer, and playwright, remains the master of comedy. He introduced the single all-purpose set for the production of his plays, which combine elements of farce and comedy of manners. Later in the French Enlightenment, the writer Voltaire wrote several tragedies influenced by Shakespeare and the Greeks and also experimented with tragicomedy.

German drama developed slowly due to the fragmented governmental, religious, and cultural

nature of German-speaking Europe and was heavily influenced by touring European troupes. The most singular element of the drama was the Narr, or Fool character, who permeated their plays. In 1741 the critic Johann Christoph Gottsched, who encouraged German drama to follow the French model, initiated authentic costuming and design in the production of a Roman tragedy. Rejecting Gottsched, Gotthold Ephraim Lessing, Europe’s first dramaturge and author of the *Hamburg Dramaturgy*, encouraged the development of a distinctly German drama.

As the eighteenth century drew to a close, European drama could no longer be discussed as a singular unit. The culturally specific diversifying of theatrical styles meant that countries could claim a unique theatrical heritage while acknowledging the impact of foreign innovations, trends, and celebrities. Touring would continue to be an important element of European theatrical tradition, continuing the rise of the star system and encouraging the interplay of differing cultural styles and values.

The Baroque and Classical Revolutions in Western Music

The formal music of the early modern West was neither static nor gradual in its progression. Rather, a series of revolutions in style and form characterized Europe’s musical development. As the hegemony of the medieval church began to fragment during the Reformation, kings, noblemen, and church authorities all commissioned music that reflected their interests. Far from discouraging the composition of church music, the Reformation, in establishing several variants of Christianity, multiplied the number of patrons

of church music. Some composers were satisfied merely to fulfill their commissions, but others sought to deepen the emotional content of music. This desire for emotionality ushered in the Baroque era around 1600.

Heirs to the Reformation, Baroque composers excelled in all forms of church music. Those in Catholic lands composed innumerable masses, although perhaps none equaled the *Mass in B minor* (1733–1749) by Johann Sebastian Bach, a Lutheran. Catholic composers, aware of the Church's devotion to Mary, wrote choral music to her, Claudio Monteverdi's *Vespers to the Blessed Virgin* (1610) being one famous example. In Catholic and Protestant lands composers set the events leading to Jesus's death (the Passion) to music. At the apex of this genre are Bach's *St. John Passion* (1723) and *St. Matthew Passion* (1729). Although not necessarily a religious form, the oratorio was in the hands of George Frideric Handel, a vehicle for narrating events in the Bible. *Messiah* (1741) remains Handel's most popular oratorio. In Protestant lands composers used the cantata to set passages in the Bible to music. Bach wrote more than 200 cantatas, most of them while he was cantor at St. Thomas's in Leipzig.

The Reformation was one stream that nourished the Baroque; the other was the Renaissance, whose secular spirit translated into the composition of secular music. The first years of the Baroque witnessed the rise of the opera. In 1597 poet Ottavio Rinuccini composed *Dafne*, the first opera. Early opera lacked dynamism and emotional intensity, qualities that Monteverdi infused into *Orfeo* (1607) and his later operas. Baroque opera included dances, which were the origin of ballet. Composers further added comic vignettes between acts to the score, and these grew into comic opera.

In addition to vocal music, the Baroque witnessed an outpouring of instrumental music. The dance suite was not, contrary to its name, suitable for dance but instead gave composers a vehicle for virtuoso display. The number and arrangement of suites varied. In the *Partitas* (1720) for violin and the *French Suites* (1722) for harpsichord, for example, Bach used virtuosity to heighten the emotional content of the dance suite. The concerto, another form new to the

German Baroque composer Johann Sebastian Bach, portrait by Elias Gottlieb Haussman, 1764. (Jupiterimages)

Baroque, pitted a single instrument against the orchestra. Pioneers in this type of music, composers in Italy allotted three movements to a concerto, the first and third being fast and the second slow. Antonio Vivaldi's *Four Seasons* (1725) are perhaps the most popular concertos of the Baroque era. A variant of the concerto for solo instrument and orchestra, the concerto grosso pitted two or three instruments against the orchestra. Bach's *Brandenburg Concertos* (1721) are surely the most popular concerto grosso. At the other extreme are Arcangelo Corelli's concerto grosso (1713). Popular during the Baroque, they are seldom heard in concert today.

Musicologists mark the end of the Baroque with Bach's death in 1750. Thereafter a period of experimentation gave rise to the Classical era. While seeking to preserve emotional intensity, composers in the second half of the eighteenth century turned away from what they felt was the artificial style of Baroque music. In emphasizing clarity and simplicity, these composers replaced the Baroque with the Classical era.

➤ BACH'S GOLDBERG VARIATIONS

The story of the genesis of Bach's Goldberg Variations comes from an early biography. Scholars think the story fanciful. Bach did not, for example, dedicate the variations to the Keyserling, as was his custom when dealing with an aristocratic patron. Rather, Bach gave the Goldberg Variations to his wife.

"The Count (Keyserling) was often sickly, and then had sleepless nights. At these times Goldberg, who lived in the house with him, had to pass the night in an adjoining room to play something to him when he could not sleep. The Count once said to Bach that he should like to have some clavier pieces for his Goldberg, which should be of such a soft and somewhat lively character that he might be a little cheered up by them in his sleepless nights. Bach thought he could best fulfill this wish by variations, which, on account of the constant sameness of the fundamental harmony, he had hitherto considered as an ungrateful task. But as at this time all his works were models of art, these variations also became such under his hand. This is, indeed, the only model of the kind that he has left us. The Count thereafter called them nothing but 'his' variations. He was never weary of hearing them; and for a long time, when the sleepless nights came, he used to say: 'Dear Goldberg, do play me one of my variations.' Bach was, perhaps, never so well rewarded for any work as for this: the Count made him a present of a golden goblet filled with a hundred Louis d'ors. But their worth as a work of art would not have been paid if the present had been a thousand times as great."

—Christopher Cumo

Source

Johann Nikolaus Forkel, *Johann Sebastian Bach: His Life, Art, and Work* (New York: Vienna House, 1974).

Although religious music did not disappear, it was now subordinate to secular music. Classical composers insisted on writing absolute music, music that had no association with an idea or object. Ludwig van Beethoven, however, departed from this ideal with his *6th Symphony* (1808) in which he aimed to evoke nature. Gone was the

dance suite of the Baroque and in its place was the sonata cycle of three or four movements. The first and fourth movements were fast, the second movement was slow, and the third movement was a minuet. Classical composers exploited the sonata cycle in fashioning symphonies. Franz Joseph Haydn wrote more than 100 symphonies, Mozart wrote 41, and Beethoven wrote 9. Classical composers retained the concerto while introducing new instruments as the solo. In place of the harpsichord, Classical composers wrote concertos for the piano, an instrument that, although invented in 1709, had been neglected during the Baroque period. In his 27 piano concertos, Wolfgang Amadeus Mozart enlarged the orchestra, lengthened the movements, and deepened the emotional content of music. Notable for their emotionality are his two concertos in a minor key, the D minor (piano concerto 20) and the C minor (piano concerto 24 in 1786). Beethoven wrote five concertos, the last being the *Emperor Concerto* (1809). Classical composers also retained opera. As he did to so many other forms, Mozart deepened the emotional intensity of opera. *The Marriage of Figaro* (1786), *Don Giovanni* (1787), and the *Magic Flute* (1791) mark the apex of Classical opera.

In the short term Classicism gave rise to Romanticism. In the coupling of a large orchestra with a chorus in his *9th Symphony* (1824), Beethoven anticipated the grandiose scale of music that was a signature of Romanticism. In this sense he bridged Classicism and Romanticism. In the long term the Baroque and Classical eras have won an audience larger than their composers could have imagined. The concert hall is merely one venue for the enjoyment of Baroque and Classical music. In the nineteenth century enthusiasts could listen to Baroque and Classical music on phonograph records and in the twentieth century on cassette tape and compact disc (CD). Manufacturers have priced the CD within the means of most consumers and have recorded an encyclopedic variety of music. It is possible, for example, to choose among dozens of recordings of Bach's *Goldberg Variations* (1741). Judging by CD sales, Baroque and Classical music are more popular than at any time in the past.

The Highest Form of Flattery— The Influence of European Art on Mughal India

European art played a primary role in the development of Mughal artistic production together with Indian and Persian influences. It was one of the major sources of inspiration for the definition of the Mughal aesthetic canons, providing to the Mughal artists models, subjects, and techniques.

From the sixteenth to the seventeenth centuries the Mughal empire developed not only as a strong political center but also as a highly defined cultural and artistic entity. In order to foster contact with the West, diplomatic relations were established first between the Ottoman empire, the Safavid power in Central Asia, and then Europe. This was further cemented with a consequent important circulation of gifts and embassies among all these regions. By that time the Indian Ocean was a major conduit for the global market, even for the exchange of artwork. Scholars know from various sources that

the ocean represented one of the main channels for the circulation of models. In addition to the aforementioned diplomatic relations and the circulation of models, the arrival of the first Portuguese delegation through the Indian Ocean and its consequent settlement along the Indian coasts was probably one of the strongest vehicles for the European influence.

Retracing the steps of the Mughal domination and the character and taste of the main sovereigns who succeeded to the throne, it is quite easy to recognize the entity and peculiarity of the European influence in the different artistic fields.

In architecture, the European models seem to have arrived a little later. Until the production patronized by Akbar (1556–1605) a strong Hindu connotation of structures appears as predominant, leaving only a minimal space for European influences in both decorative schemes and elements. It was only under Jahangir (1605–1627), triumphing then under Shah Jahan (1628–1657), that the Mughal monuments began to show a clearer presence of decorative schemes and motifs ascribable mainly to European influences. The use of flowers in decoration, their shapes and arrangement, could be an emblematic example. Their use, common in both the Mughal imperial production and in the Ottoman architecture, seems to be ascribable to a frequent provenance from the European herbals, identified as main

► COPIES AND ALLEGORY IN JAHANGIR'S PICTURES

Prince Jahangir was undoubtedly the first Mughal to manifest a strong and unusual interest in Europe and its art. Close contact with traders and missionaries increased his collection of Western pictures, engravings, and prints with both secular themes and religious subjects, while the documented presence at court of foreign artists contributed to consolidating the appreciation of Western production in Mughal India. Portraits of the emperor, painted under commission, are examples of the imitation of European models and also illustrate the assimilation of symbols and elements that enriched the representation of sovereignty and authority.

The motif of the round halo, a symbol of the sun, originating in Persia and already applied in the Gandhara sculptures, probably reached the

Mughal's ateliers through European objects of art. Elements such as angels and cherubs were also assimilated from Renaissance Europe. Moreover, the sovereign is often depicted standing on or holding a globe, again a symbol derived from Europe and associated with a lion, representing his universal power and majesty. Some Western religious themes, like the Crucifixion or the Ascension, are depicted in the context of Mughal pictures. Together with Western people, representatives of European states, or monarchs, these scenes were painted at the court of the great sovereign, copied from the European originals, or, as in the case of many engravings, directly included in Jahangir's albums.

—Sara Mondini

sources of inspiration. Also, the *parchin kari*, or inlaid marble technique, largely used even in the Taj Mahal to represent flowers, corresponds to the Italian technique known as *commesso di pietra dure* (composition of hard stones). The real origin of the technique is still debated among scholars. However, it could have found application in India perhaps due to the presence of Italian craftsmen at the Mughal court.

It was in painting, however, that the influence of European art illustrates the greatest impact, in some cases even through the actual imitation of certain subjects. The study of the Indian miniature is usually regarded as a fundamental source to reconstruct the development of painting, and these types of illustrations, which often decorated Buddhist manuscripts, represent a source of evidence to trace the development of Indo-Islamic paintings.

Already with the beginning of the reign of Akbar (1556–1605), Hindu artists under Persian influence developed a new and realistic style of painting in which the impact of European art played a certain part. Subsequently, in later decades it grew in prevalence. The assimilated European elements are distinct from the Persian and the Chinese characteristics that also enriched the development of Mughal style and technique.

The European works of art brought to the Mughal court, often as embassy gifts or through the mediation of Jesuit missionaries, were

studied and regularly imitated by Indian artists and were the subject through which techniques were rendered according to their aesthetic norms. Under Jahangir (1605–1627) the characterization, the study of anatomy, and physiognomy were increasingly emphasized, and the realism of the result did not exclude the proper use of symbolism and allegory in painting. The painters of Shah Jahan's atelier are examples of this development. While the Dutch influence was notable, the role of Italian Mannerism also had a primary role. The artists of the Mughal atelier through the consolidation of *chiaroscuro* try to depict night scenes inspired also by European Baroque pictures.

■ Introduction: Global Cultural Exchange

The biological exchanges triggered by the contact between the Old World and the New World had profound consequences on world history, far more than similar preexisting processes within the Afro-Eurasian ecumene. The term “Columbian Exchange,” coined by notable historian Alfred W. Crosby in his book of the same name (1972), denotes this process of diffusion of plants, crops, diseases, and human migration that began with Christopher Columbus's voyages of exploration, which subsequently extended globally. Staple crops from the Ameri-

cas (e.g., potatoes, manioc, tomatoes, and peppers) spread to Europe and from there to the Middle East, India, and China, thereby influencing culinary tastes and dietary habits. Moreover, European crops and livestock (e.g., wheat, vines, chickens, horses, cattle, and sheep) were sent to the Americas, drastically increasing food supplies. However, the Columbian Exchange also brought disease to the Americas, most notably smallpox, which annihilated tens of millions of indigenous peoples who never developed immunity to such pathogens. Many of these people

died of European diseases carried through indigenous networks, while having never personally met a European. Nonetheless, the Columbian Exchange was a significant historical process in world history that radically increased the wealth of Europe, fueled global commerce, and had significant effects in the dietary habits of peoples the world over, triggering population growth throughout much of the globe.

The cultural implications of the Columbian Exchange were also significant in terms of altering Old World paradigms and triggering global labor migrations, shifting the centers of trade to the Atlantic world from the Mediterranean littoral and the Middle East as a result of human migration exchanges. The establishment of European colonies in the Americas also led to the development of the Atlantic slave trade for the purposes of creating cash crop plantations in the Caribbean, southeastern North America, and Brazil. European immigration from Britain and Spain drastically altered the demographic characteristics of the Americas, as swaths of indigenous Americans died due to disease. Christianity, in both its Protestant and Catholic varieties, entered the Americas, influencing and syncretizing with indigenous American religions and folkways. The notion that older scientific and religious worldviews had not accounted for the New World also fueled intellectual change as Aristotelian and medieval paradigms were questioned by European scholars (i.e., Montaigne). The Old World also experienced the infusion of wealth from the Americas, allowing major European powers with newfound wealth to engage the Ottoman empire and further expand their influence in southern Asia and the peripheries of China, Africa, and Oceania. Global commerce gradually shifted from the center of Afro-Eurasia, characterized by Asian land routes and Indian Ocean and Mediterranean trade networks, and shifted it to the Atlantic as Spain, the Low Countries, and England emerged as new entrepôts of world trade. While this process had preceded the Columbian Exchange as a result of Portugal's forays into Africa and southern Asia, it was rapidly accelerated with the entry of the Americas into this new economic world system. This newfound wealth from the New World allowed Europe to develop into an economic powerhouse

vis-à-vis India, China, and the Ottoman empire, shaping the destinies of Spain, Portugal, the Netherlands, England (Britain after 1707), and France as world powers. While Asia remained an integral center of the world's wealth and trade during this period, the infusion of American goods and wealth set the stage for the emergence of European power in later centuries.

—*Abraham O. Mendoza*

Columbian Exchange and Disease

The incidence of epidemics in world history leading to the deaths of millions of people is not unique to this period. The Justinian Plague (named after the Byzantine emperor) of late antiquity and the Black Death (in its various manifestations of bubonic plague, pneumonic plague, and septicemic plague) of the late medieval period led to the destruction of large swaths of the population of the Afro-Eurasian ecumene, with recurrences of the plague lasting well until the eighteenth century. However, increasing contact between the Old World and the New World following Christopher Columbus's "discovery" of 1492 led to the greatest incidence in demographic change in the New World that was due not only to the migration of peoples but also to the related migration of pathogens. The Columbian Exchange of disease, mostly in the form of smallpox, measles, malaria, and the plague, among other pathogens, and along with other contributing factors, led to the deaths of an estimated 100 million people in the Americas. These catastrophic losses of the indigenous population of the Americas, over approximately 400 years, had political, economic, and social consequences for this period.

While contact with Old World diseases is a factor for the demographic depletion after 1492 in the Americas, other factors also contributed to the mass death of millions of indigenous Americans. Incidences of warfare, dispossession of property, interbreeding, and mass killings perpetrated by Europeans against indigenous Americans also contributed to the massive demographic loss in the Americas. The introduction of pathogens into societies with no immunity in tandem with European incursions (and Africans

► HISTORICAL DEBATE OVER THE IMPACT OF DISEASE ON POST-COLUMBIAN INDIGENOUS SOCIETIES

While historians do not disagree that the introduction of diseases contributed to the extermination of millions of indigenous Americans and the collapse of their civilizations, there are disagreements as to the level of complicity of other factors. It is argued that placing the onus of the collapse and conquest of the Americas on the spread of diseases minimizes the level of agency on the part of European conquest and warfare. This narrative, purported by many environmental historians, proposes that it was biological immunity that doomed indigenous populations to their collapse. However, other historians, such as Alfred W. Crosby, suggest that while “virgin soil epidemics” caused the destruction of millions of Americans after 1492, other factors also contributed to the collapse of these societies. As such, all these factors have to be taken into account when discussing the history of the mass death of indigenous Americans after contact with Europeans and Africans, lest it not offer a fuller perspective of the multicausal confluence of historical processes.

—*Abraham O. Mendoza*

brought as slaves) and conquest contributed to the deaths of millions. Outbreaks continued as diseases new to the Americas were introduced and subsequently spread through trade routes with other indigenous groups. Some scholars suggest that some indigenous American societies never actually came into contact with Europeans or Africans and yet suffered tremendous losses after the introduction of diseases into their communities.

Historians speculate that the lack of immunity to these diseases given the lack of contact that existed led to the introduction of such pathogens into long-established societies with little to no understanding of the occurrence of such diseases. Known as virgin soil epidemics, meaning that the populations exposed to them had no immunity to them, these diseases did have historical precedents in terms of their impact on existing societies. Much like in Europe and Asia during outbreaks of the Black

Death, entire communities suffered outbreaks en masse, with large swaths of the population dying. Severely weakened by disease and with segments of the productive population (such as those who procure food and forage) dead or weakened, the pandemics along with other factors illustrate how these American societies were depleted over time. This contributed to the collapse of the local and regional economies, political structures, and societies as a whole.

Scientists and historians have meticulously compiled lists of diseases and epidemics that were introduced in the Americas by Europeans and Africans after 1492. While some of these are based on speculation and hypotheses, others are based on empirical archaeological and historical research and data. The major diseases that afflicted the New World that originated from the Old World are the following: smallpox, diphtheria, measles, whooping cough, bubonic plague, malaria, trachoma, cholera, typhoid fever, scarlet fever, yellow fever, dengue fever, influenza, and dysentery. The overwhelming amount of diseases that arrived in waves and the lack of immunity on the part of indigenous Americans illustrate the level of the impact that Columbian exchanges of pathogens had on New World populations over the next 400 years. Pockets of isolated communities, once in contact with Europeans, Africans, or other Americans, were also prone to outbreaks as recently as the mid-twentieth century.

According to some, the Europeans not only brought diseases to the New World but also brought one very virulent disease back with them: syphilis. The debate over the origins of syphilis has mostly been divided into two camps: those who believe that syphilis did not exist in Europe before Columbus's first voyage to the New World and those who believe that it did. In recent years another side has popped up, one that believes that while syphilis did exist in Europe before 1492 it was a different strain of the disease and that the American strain was much more virulent. Although neither side has been able to prove its theory conclusively, it is evident, based on the documents, that the venereal form of syphilis did not appear in Europe until the sixteenth century. There is no mention of a disease with symptoms similar to that of syphilis before

1492, and Europeans of the time found evidence of syphilis among the indigenous populations. In addition, forensic anthropologists have found evidence of syphilis in pre-Columbian skeletons.

The relationship between the depletion of indigenous Americans and the onset of the transatlantic slave trade is also illustrative of the impact of Old World diseases on the Americas. The inability to procure sufficient amounts of labor from the Americas by Europeans, as these societies collapsed as a result of conquest and disease, was offset by the influx of millions of black African slaves forcibly brought to the New World. Black Africans further introduced more diseases, which exacerbated the already catastrophic situation of the indigenous Americans. As African slaves were seen as amenable and resistant to tropical conditions and diseases by their European oppressors, they were coerced to work for the cultivation and production of cash crops.

Cultural Exchange between Europe and the Islamic Middle East

Although the image of relations between the Islamic states of the Balkans, the Middle East, and North Africa and the Christian states of Europe in the early modern period is often one of hostility, there was also a great deal of social and cultural exchange.

There were numerous avenues for contact and exchange. European and Islamic rulers sent embassies to each other that often attracted a great deal of popular interest. There was a constant interchange of population through the pirate vessels and slave markets of the Mediterranean. The numerous Christian converts to Islam and the much smaller number of Muslim

converts to Christianity brought the knowledge of their old societies to their new. Converts from Christianity, or “renegades,” were a major segment of the population and the ruling elite in the semi-independent North African cities such as Tripoli and Algiers and also supplied some of the most famous captains of the “Barbary corsairs.” Christian subjects of Muslim rulers retained contacts with their coreligionists outside the Islamic world. The religious divisions of Western Christians helped foster interest in the Eastern churches under Muslim rule and in the greater degree of religious toleration practiced in Islamic empires. Christian merchants and scholars sought profit and knowledge in the lands of Islam. Although Muslims were less likely to enter Europe for trade, there was a long-standing community of Ottoman Muslim merchants in Venice as well as communities of Christian Ottoman subjects, including Greeks and Armenians. Jews, marginal in both Christian and Islamic societies, traveled between them.

Cultural contact broadened Christian knowledge of the Islamic world and its customs. The Quran and other Islamic texts became available in numerous editions in European languages. The Ottoman Turks, on the advance against European Christendom in southeastern Europe and the Mediterranean until the late seventeenth century, were the object of great interest. Numerous accounts of the lands of the “Grand Turk” from Christian travelers, diplomats, and captives poured from European presses. The “Sophy” or Safavid ruler of Persia—viewed as a possible ally against the Turks—also attracted much attention, as did the “Mogul” of India. There were far fewer Islamic travelers in the Christian world than vice versa, and the few accounts of Christendom written by Muslims could not be as widely distributed, given the Islamic world’s rejection of the printing press. The Muslim interested in the Christian world had far less available information than his or her Christian counterpart.

Numerous Middle Eastern cultural practices were transmitted to the West. Prominent among them was coffee drinking and the institution of the coffeehouse, introduced by the seventeenth century. Early coffeehouses were frequently identified with the Middle East and its peoples. The first English coffeehouse, the

THE RENEGADE JOHN WARD

Some of the renegades, converts from Christianity to Islam, who became corsairs in North Africa became almost legendary figures to the Christian societies they left behind. John Ward (ca. 1553–1622), a poor English sailor and fisherman, became a Muslim, taking the name Yusuf Reis, and a renowned pirate in Tunis, operating under an agreement to share his loot with the ruler of Tunis, Uthman Bey. Ballads were sung in England of Ward's battles and the luxuries of his palace, with one registered as late as 1680. The ballads skipped over Ward's conversion, presenting him as a successful pirate. The English playwright Robert Daborne, by contrast, emphasized Ward's conversion in his 1612 play *A Christian Turn'd Turke*. Daborne painted Ward not as a dashing hero but as a corrupt villain and ended his play with the renegade being torn in pieces, although Ward was still alive at the time.

—William E. Burns

Angel, founded in Oxford in 1650, was owned and operated by a Lebanese Jew. The Middle East also had a long-lasting influence on Western male dress, including the introduction of the vest. Smallpox inoculation was an Eastern practice that became very popular in Europe in the eighteenth century.

Western cultural practices were also adopted in the Middle East. Some of these, such as tobacco smoking, had to do with the new American crops that entered the Middle East through Europe. By contrast with the popularity that tobacco attained despite the fierce opposition of many Muslim religious scholars, the fifteenth-century Ottoman interest in Italian Renaissance painting and architecture fizzled out with the increasing cultural Islamization of the empire in the sixteenth century. However, there was also interest in European technology, particularly military technology. Westerners helped cast the guns with which Sultan Mehmed II took Constantinople in 1453. The French convert Claude Alexandre de Bonneval (1675–1747), a former officer in the French and Austrian armies, helped reorganize the Ottoman artillery. Barbary corsairs of northern European origin were often

credited with introducing northern naval technology to the Islamic world.

Non-Muslim Middle Eastern minorities were the most exposed to cultural change from the West. The Jews exiled from Spain in 1492 entered the Islamic world in great numbers and brought many of their own distinctive cultural traits with them, such as the languages of Ladino and Haketia and the mystical Kabbalah. The Catholic Church was a growing presence among Christian communities in the Middle East. Maronite and Greek colleges, to train priests in those churches who would acknowledge the supremacy of the papacy, were founded in Rome in 1684. In the eighteenth century a Maronite Arab from Lebanon, Yusuf al-Simani (1687–1768), became a Vatican librarian.

Early European Cultural Influences in India

The development of the East India trade opened a direct connection between India and Europe for the first time since the seventh century CE. Some Western influences had entered India in ancient and classical times, including Greek art and astronomy. Different Muslim empires also provided important links between India, Asia, and Europe. However, the most important influx of European ideas into India began during the sixteenth century.

In the sixteenth century, individual Portuguese merchants and mercenaries traveled all over South Asia serving as foreign advisers at Indian courts or establishing renegade settlements such as Hooghly in eastern India. These foreigners posed no political threat at the time and were mainly seen as useful conduits for the transmission of the outside world's knowledge, especially military expertise. In addition to the military knowledge brought by European soldiers and merchants, a wide range of Western

► THE TOPAZES—PORTUGUESE NAMES, CHRISTIAN IDENTITIES, AND INDIAN CUSTOMS

Like other parts of the early modern world that felt the effects of European expansion, India mainly attracted male adventurers. European women really did not begin to travel to India in significant numbers until the eighteenth century, and even so the culture of the East India trade was overwhelmingly masculine. As in the New World, concubinage and interracial marriages were accepted as a matter of course, especially in the Portuguese settlements during the sixteenth century. The inevitable result was the formation of a class of Indo-Portuguese descendants of cross-cultural unions. Such people usually sported Portuguese names and practiced Roman Catholicism but for the most part looked and lived like other Indians. Their collective name, Topazes, referred to their use of hats rather than turbans, the hat being the quintessential mark of the European, who often was called a *topi-wallah*, or “hat-man.”

There were flourishing Topaz communities in every port town in South India in the eighteenth century, and as the power of the Portuguese crumbled, these people found a new niche for themselves as local guides and interpreters for the Dutch, French, and English. All of the East India companies employed Topazes as soldiers, sailors, and often low-level bureaucrats. The daughters of Indo-Portuguese families, meanwhile, often married Dutch, French, and English military officers and merchants, thus securing the community’s place in the emerging colonial social order. Indeed, in most European settlements, the Topazes outnumbered the foreign population by five or ten to one, and it is unlikely that the East India companies would have been nearly as successful without their contributions.

—James Hoover Frey

cultural influences also followed in the wake of their activities.

The conversion of hundreds of thousands of primarily low-caste and outcaste people in South India to Roman Catholicism stands out as one of the most enduring legacies of Portuguese and later French influence. Missionaries, however, often preferred to work far from the main European enclaves and the meddling influence of officials, pursuing a plan of proselytization that had nothing to do with colonial policies. In southern Tamil Nadu, Jesuits working in and around the court of Tirumala Nayaka of Madurai in the late seventeenth century had a major enduring impact on Tamil culture by developing a type font to enable the Tamil script to be used in printing presses. Their work was carried further in the early eighteenth century by Danish Lutheran missionaries working from the Danish East India Company’s settlement at Tranquebar.

For the most part, the spread of European cultural influence was haphazard and subject to the passing fancies of individual Indian borrowers. Indigenous sources often refer to *farangi* (foreign) objects, clothing, instruments, music, and people, especially in the context of royal courts, and we know that different East India

companies sent Indian rulers a steady stream of gifts throughout the seventeenth and eighteenth centuries in an effort to impress potential business partners and to showcase European wares. Elements of European material culture, however, usually were assimilated according to existing Indian tastes. One ruler in South India, Marthanda Varma, amassed a stunning collection of French and Dutch mirrors at his palace in Travancore; these mirrors were used not to reflect people’s images but instead to cover and decorate entire walls, to enlarge rooms, and to bring sunlight into dark interiors. Miniature painters for the Mughals adapted European ideas to some extent, and European missionaries debated religion at the court of the Mughal emperors at Delhi as well.

Beyond the royal courts of early modern India, perhaps the most profound European cultural influences were not really European at all but rather products of the global system of cross-cultural exchange through which European shipping tied together the world’s economic and cultural zones. During the sixteenth century Indian spices, such as black pepper, transformed European kitchens. Yet at the same time, European traders were bringing American plants and

spices, such as the tomato and the red chili, to India, transforming Indian cooking. Curried dishes and *chai* (hot milk-tea) are symbols of Indian culture today, but both curries and *chai* were influenced by European trade in India.

European cultural influence in India, however, was never fully respectable, which to some extent explains the fleeting, faddish manner in which Indians adopted European cultural practices and material culture. There is abundant evidence that the popular conception of the *farangi* was strongly negative. Hindus considered most Europeans ritually polluted outcasts because, like untouchables in Indian culture, they ate meat and consumed liquor. However, popular condemnation went further than that: Europeans were violent and licentious. They wore wigs powdered with rotting flour and made of other people's hair (extremely problematic for many Indians), they wore leather boots and hired servants who were outcasts, and they did not clean themselves properly after bodily functions. In order to interact intimately with Indians, Europeans had to adopt indigenous ways, for the Indian elite refused to come down to their level.

Given that most Europeans, being polluted, could not even share a meal with caste-conscious Hindus or even stand in close proximity to them, the opportunities for significant cross-cultural exchange were extremely limited. It is not surprising, therefore, that Europeans had much more contact with Indian Muslims during the early modern period. Rules governing ritual purity did not stand as a bar to social contact in an Islamic context. Among Hindus, meanwhile, most cross-cultural experiences with Europeans were limited to members of the lowest castes of the social order, especially those who lived in coastal cities and worked as personal servants or employees of the East India companies. Even in these cases, however, European culture tended to be mocked rather than adopted. While stationed with his regiment at Madras in the 1780s, Innes Munro chanced to walk into an Indian theater in a narrow lane of the Black Town, the city's Indian quarter, where he discovered, to his astonishment, that the people were watching a Tamil play in which the actors dressed as

Europeans and ridiculed the East India Company's policies and foreign ways in general.

Derision, however, was not the only response that ordinary Indians displayed toward European culture. Sepoys, or Indian mercenary soldiers, and the literate indigenous bureaucrats who worked for the East India companies often admired what they perceived to be the manliness of European military culture, the European talent for organization and order, and military technology, including huge warships and star-shaped forts bristling with cannon. When we bring all of these Indian perceptions of Europeans together into a single focus, we find ourselves looking at a bundle of contradictions: Europeans were powerful but ignorant and inept; they often came from a ruling class but at the same time lacked social status or appropriate manners. Above all, it seemed to most Indians that Europeans were people without religion, history, or connections. In short, Europeans in the context of early modern India represented complex and contradictory identities.

Early Modern European Cultural Understandings of Hindu India

Although Europeans had limited cultural contact with India since the ancient world, the circumnavigation of Africa by the Portuguese sailor Vasco da Gama (ca.1460–1524) in 1498 enabled direct European contact with India without the traditional intermediary of the Middle East. Ideas about the wealth of India handed down from medieval travelers such as Marco Polo continued and helped motivate the voyages of da Gama, Christopher Columbus, and other European explorers.

European knowledge of India came from many sources in different parts of India, which added to the overall impression of Indian cultural diversity. It proved far harder for Europeans to form a unified image of South Asia (a large and diverse region) than it was for them to form images of China and Japan (which Europeans saw as more culturally unified). The Portuguese outpost at Goa was particularly significant in contacts between India and the West. Catholic missions were another important intermediary, particularly the Jesuit mission to the Delhi court of the “Great Mogul [Mughal],” the Muslim ruler of most of India. The Mughal ruler Akbar (r. 1556–1605), whom the Jesuits hoped in vain to convert, acquired a European reputation as a philosopher-prince. Continued European interest in Mughal rulers can be seen in the English poet John Dryden’s play *Aurangzebe* (1676) based on the life of Dryden’s contemporary, the Emperor Aurangzeb (r. 1658–1707). The Muslim Aurangzeb, like the Hindu ruler of the south Indian state of Vijayanagar, was often treated by Europeans as a prototypical “Oriental despot.”

Jesuit writers were particularly interested in Indian religions but also wrote on politics and culture. They were divided on whether Indians could, like the Chinese and Japanese, be regarded as “civil” peoples who, despite their religious errors, followed reason or whether they were barbarians like the indigenous people of Africa and North America. Religiously, Hindu India was viewed as presenting the principal opportunity for Christian conversions, as few hoped to convert the Muslim population in the region. Hinduism posed the problem for Europeans of a

society that was highly developed but continued the “primitive” practices of polytheism and idolatry. Indian paganism was the subject of a debate between the Jesuit missionaries Robert de Nobili (1577–1656), who dressed and acted like a Brahmin and accepted many aspects of Hindu tradition in hopes of winning converts, and Goncalo Fernandes, who viewed Hindu tradition as suffused with paganism and claimed that true Christian conversion would involve adopting European customs. The German Jesuit Athanasius Kircher (1601–1680) attempted to incorporate the religion of the Brahmins into a world history of idolatry influenced by Neoplatonism in his *China Illustrata* (1667). Jesuits also pioneered the study of Indian languages among Europeans. The Jesuits Heinrich Roth (1620–1668) and Johann Ernst Hanxleden (1681–1732) were the earliest Sanskrit grammarians among Western scholars. The ideal of the wise, philosophical, and fundamentally secular Brahmin can be traced to ancient Greek and Roman accounts of India, and European enlightenment writers such as Voltaire continued to use it as a literary convention. However, greater western knowledge of Indian religions led to a less idealized version of the Brahmin.

Although there was little direct translation from Indian languages until the eighteenth century, one influential work had followed a complicated route from Sanskrit through Middle Eastern languages to European ones. The *Panchatantra*, a collection of fables and tales, had been translated into Persian, Syriac, and Arabic in the Middle Ages and eventually reached Christian Europe as the *Fables of Bidpai* (or “Pilpay”). Francesco Doni (1513–1574) published an Italian translation from the Latin in Venice in 1552 that became the source of the earliest English version, the prolific translator Sir Thomas North’s *Morall Philosophy of Doni* (1570). Like other translators, Doni and North presented the collection both as entertaining stories and as wise moral counsel. The fabulist Jean de La Fontaine (1621–1695), one of the most popular French writers of the seventeenth century, credited Pilpay as a principal source of his *Fables*.

It was also through the Islamic world that India had made perhaps its most important

contribution to European civilization, the numeral system known in the west as Arabic numerals whose use was increasing in the early modern period. Direct contact with India broadened India's impact on European science. As elsewhere in the world, Europeans were interested in natural history and the medical applications of native plants. Goa was the base of the Portuguese physicians Garcia d'Orta (ca.1500–ca.1568) and Christovao da Costa (ca.1515–1580), who published on the drugs and remedies of India. Their works relied on discussions with native informants, particularly the Ayurvedic physicians of Goa. An Italian visitor to Goa, Filippo Sassetti (1540–1588), translated an Ayurvedic compendium, the *Nighantu*, from Sanskrit to Italian. A Dutch governor of Malabar, Henricus Van Rheede Van Draakenstein (ca.1637–1691), employed Indian physicians to help prepare a 12-volume botanical compilation, *The Garden of Malabar in India*, published in Amsterdam from 1678 to 1703.

The Making of an Islamic Peasant Culture in Bengal

One of the most intriguing questions in Indian history concerns the demographics of conversion to Islam. Why did mass conversion to Islam occur only in the far western and far eastern regions of India? The question is all the more interesting because all of these areas of intensive Islamization lie outside the heartlands of the major Islamic empires established in South Asia during the medieval and early modern periods. Throughout most of India during the early

modern period, Islam was the religion of a small elite minority and of a few communities of immigrant minorities or low-caste converts from Hinduism. Indian Islam was primarily an urban faith, the religion of men in power: rulers, administrators, soldiers, and their clients. Only in Sind, western Punjab, Kashmir, and Bengal did the spread of Islam penetrate village culture and result in the mass conversion of peasants and even laborers. Sind, of course, was the first part of India encountered by Muslim armies, while Punjab and Kashmir were situated close to central Asian trade routes and subjected to Islamic influences for centuries. The mass conversion that occurred in Bengal, however, is harder to explain, for the swampy lowlands of Bengal—what is now the populous country of Bangladesh—were one of the last areas to be subject to the rule of expanding Muslim empires.

The spread of Islam in the area during the late medieval and early modern periods was connected with the formation of the Ganges delta and the eastward spread of Muslim agricultural pioneers. Turkish raiders reached the western borders of Bengal in the twelfth century, but permanent conquest did not occur until the thirteenth century and tended to be limited to a few cities and towns in the western part of the region. While Muslim soldiers controlled the cities, the countryside (similar to other areas in India) remained under Hindu rajas, local landlords who essentially acted and were treated like petty local kings. This political situation changed little during the early phases of Mughal rule, although other factors were significantly altered, especially in the eastern districts.

The areas of mass conversion to Islam in South Asia all have one element in common: they were all places where Hinduism was not well established and where urban life was strongly influenced by Buddhism and rural life was strongly influenced by local animistic cults. Buddhism already was in decline by the time of the Islamic conquests, and doctrinally there were few obstacles preventing Buddhists from embracing Islam. Bengal had been one of the last holdouts of royally sponsored Buddhism in India, and even where the population had adopted Hinduism, caste divisions were fairly rudimentary and rules concerning ritual purity and pollution nowhere

near as strictly enforced as in northern India. Bengali religious life was relatively unorganized, earthy, personal, and emotional, all elements that tended to promote conversion to Islam especially since Islam was brought to Bengal not by central Asian warriors interested in tax collection but instead by charismatic Sufi mystics who wanted to develop agricultural lands to support their religious communities. Local groups found it difficult to resist Islam, which on the one hand was associated with powerful new political forces and international commerce and on the other hand possessed a syncretistic side that allowed local deities to be reinterpreted, in an Islamic context, as a *jinn* (spirit).

In many ways, the process of conversion to Islam in Bengal was not unlike similar processes that had occurred earlier in the Punjab and Kashmir, but whereas the latter places were strongly influenced by central Asian culture, Bengal retained its own peculiar traditions and Islamized them in its own way. One of the most common methods of Islamization, one found not only throughout South Asia but, in fact, all over the Islamic world, was the simple identification of Allah with existing locally revered supernatural powers. In Bengal, for instance, Allah often was equated with Prabhu, the Supreme Deity, and over time these pre-Islamic entities came to be redefined on Islamic lines. When it came to assimilating local goddesses, the divine feminine represented by Isamati, Sita, or Radha—all forms of the Earth Goddess—were equated with prominent women of the prophet Muhammad's life, such as Amina or Fatima. Bengali Muslims, for instance, often referred to Fatima as the “mother of all” except her own husband, 'Ali.

Islam thus spread not by destroying Hinduism or animist religions but by taking them over, one element at a time, through a simple process of equating Islamic beliefs and practices with things that local people already believed or did. The result was the formation of a uniquely Bengali form of Islamic life, rooted in peasant ways and concerns.

As Islam took root in the hearts of people in the eastern districts of Bengal, around Dakha, especially in the seventeenth century, Mughal administrators did their best to extend royal patronage (and thus control) to the hundreds

➤ THE EASTWARD SHIFT OF THE GANGES, FRONTIER SUFISM, AND CONVERSION TO ISLAM

In the thirteenth and fourteenth centuries, the main channel of the Ganges flowed into the Bay of Bengal near what is now the town of Hooghly, near Calcutta, and the coastline lay much farther inland than it does today. The landscape extending eastward was a thinly populated semiwilderness of mud banks, marshes, mangrove swamps, and jungles. Here tribal societies only barely removed from a Neolithic level of technology supported themselves as fishermen, hunter-gatherers, cultivators, and itinerant traders. Throughout the early modern period, however, the main channel of the Ganges shifted eastward, leaving a network of narrow creeks, oxbow lakes, and low-lying marshy alluvial islands in its wake. Today a small portion of this landscape, the Sundarbans, remains, reminding us of the mangrove jungle that quickly grew up as the Ganges moved year by year, creating what has been called the Bengal “frontier.” The river also created rich new lands for farming, of course, and naturally attracted agrarian colonists. Tribal peoples furthermore were persuaded by these ecological changes to settle down as farmers, a choice further stimulated by the activities of Muslim missionaries. As a “frontier,” eastern Bengal was attractive to Sufis, or Muslim mystics, whose spiritual practices often brought them into collision with orthodox Muslims. Many mystics therefore deliberately sought out politically unorganized or marginally Islamic areas where they could experiment with different paths of personal spiritual development without risking censure or persecution.

—James Hoover Frey

of village mosques that Sufi pioneers had established during the preceding centuries. It was clear to all outsiders, however, that Islam in Bengal was very much a folk religion, much like Islam in sub-Saharan Africa, for few Bengalis were conversant in Arabic or Persian, the languages of “classical Islam,” or even in the Turkic languages. Muslim intellectuals usually preferred to express themselves in the medium of Arabic or other “learned” languages, as doing so allowed them to lay claim to *ashraf*, or gentleman status. However, many poets in Bengal, such as Abd al-Nabi,

opted to use the less acclaimed but more direct language of the masses. Nabi wrote that “I am afraid in my heart lest God should be annoyed with me for having rendered Islamic scriptures in Bengali. But I put aside my fear and firmly resolve to write for the good of the common people.” Significantly, however, Bengalis themselves did not view Islam as a foreign cultural force, for through the process of identifying Arab spiritual ideas with local equivalents, they had made Islam their own and had rooted this faith from the desert in their own watery world.

The Columbian Exchange in Southeast Asia

Unlike other world regions in the emerging post-1500s economic world system, Southeast Asia did not immediately absorb plants and animals from the Americas at the same level as Europe, East Asia, and the Middle East. The biological influence of the global Columbian Exchange did eventually have a significant impact on Southeast Asian economies and societies, albeit at a gradual rate given the increased cultural contact by Portuguese and eventually Dutch, French, and English merchants penetrating along the southern coast of the Indian subcontinent. Over the next several centuries, Southeast Asian dietary habits and agriculture did benefit from the influx of peppers, manioc, and other New World crops. However, this occurred at the expense of the gradual loss of sovereignty of the various states of the subcontinent to the encroachments of European commercial expansion.

As part of the trade networks of early modern East Asia, contact with the adjacent Chinese realms before 1500 determined the trade and commerce of the kingdoms of early modern

Southeast Asia. These realms also maintained considerable commercial contact with the Indian subcontinent. While both the Chinese and Indians were able to maintain trade and a high level of cultural influence in Southeast Asia, they were kept at arm's length militarily by regional states, such as Annam (Vietnam) and Thailand. The tropical and subtropical climatic and geographical characteristics of Southeast Asia made it a lucrative region for rice production, which became important for domestic consumption and for Indian Ocean trade. Many of the local dishes in Southeast Asia reflected regional influences from both China and India, respectively, consisting of rice dishes infused with spices.

As the Portuguese penetrated into Indian Ocean trade networks in the late 1500s, they brought crops from the Americas that they traded with Chinese and Indian merchants along their newly established trade posts in the region. Many of these merchants plied these new products into their markets in Southeast Asia, thereby introducing many of them to the palates of locals. Also, multiple varieties of chili peppers from South America were introduced in Southeast Asia by the Portuguese and incorporated into spicy dishes. Traditionally, such local dishes were made with regionally available spices attained through trade with the Indian subcontinent. After the initial introduction of peppers, over several centuries curry gradually incorporated chili peppers and thus made local regional dishes more flavorful to local palettes. However, staple crops such as maize, manioc, and peanuts did not gain prevalence in the region until well into the nineteenth century. Similar to the incorporation of these crops in China, these crops were put into marginal soils that had initially been left uncultivated. However, in South Asia the incorporation of these crops took several centuries, remaining marginal or nonexistent in the diet of locals, as they were not accepted by regional populations as staple crops, given the long-established reliance on rice.

Southeast Asian staple crops were introduced by the Dutch in the mid to late seventeenth century as they gradually displaced Portuguese political and economic influence in the region. However, most of these spices were not from the New World but instead were local

➤ CHANGES IN EAST ASIAN CUISINE

As a result of their contact with the trade networks centered on Southeast Asia, the Columbian Exchange contributed to changes in early modern east Asian cuisines in China, Japan, and Korea. While they had little to no direct contact with European traders (mostly Dutch and Portuguese merchants) during this period, they were still exposed to New World crops, which were gradually included in their myriad regional cuisines. In China, the sweet potato effectively became a major staple crop after its introduction in the mid-1500s. Spices, most notably peppers from the Americas, also found their way into east Asian dishes. Other items like potatoes, tomatoes, and peanuts were incorpo-

rated into regional cuisines over a longer period of time. Cultural exchanges with Southeast Asia and South Asia and greater demand for products from these regions that had been established in prior centuries ensured that exposure to new crops and new dishes would have long-term developments in cuisines, much like the potato in Europe that was slowly adapted in relation to economic needs of the populace. For example, while rice remained a major source of protein as an East Asian staple during this period, maize and sweet potatoes gained in popularity, as they were seen to be amenable to regional soils in times of hardship and famine.

—Abraham O. Mendoza

spices produced en masse. As the Dutch East India Company (VOC) penetrated Southeast Asia in the late seventeenth and early eighteenth centuries, particularly Indonesia, it also contributed to the establishment of cash crop plantations, finding the climate and soil of various tropical regions ideal for their cultivation. Mainland Southeast Asia found itself mostly free from European incursions and political domination until the nineteenth century but was still subjected to commercial transactions by European traders, who continued to introduce New World crops over the centuries.

Much of the biological exchange that Southeast Asia experienced, given the widespread diffusion of American crops after European settlement known as the Columbian Exchange, did in fact occur over a long period of time spanning several centuries rather than in the short term. Similar to developments in Europe and China, the Southeast Asian region was slow to acculturate to American crops unless severe climatic or drought conditions necessitated doing so. Moreover, European trade and colonialism played a larger role in the infusion of American crops than local innovations perhaps with the exception of American spices, which were incorporated into Southeast Asian cuisines. However, in the long term, as a world region Southeast Asia developed intense cultivation of American staple crops such as peanuts, manioc,

and maize in regions where soil and climatic conditions permitted.

The Columbian Exchange and the Mediterranean

Humans have been intentionally dispersing plants and animals from their native habitats at least since the advent of agriculture and domestication about 10,000 years ago. In prehistoric times, cereal crops like barley traveled with human populations westward from the Fertile Crescent to Europe. Throughout history, broad exchanges of species used for food or labor, along with attendant microorganisms, have followed the movement of peoples and empires. One might speak of an Alexandrian Exchange when spices from Asia were introduced to the West and an Islamic Exchange when foods such as rice, lemons, spinach, artichokes, and eggplant could be found cultivated from Spain to India. Such plants were especially easy to grow in regions at a comparable latitude and similar topography and climate.

➤ MEDITERRANEAN CUISINE

Imagine Italian cuisine without tomatoes and peppers or Spanish cooking without dried chili powder and tortillas. This was the case long after direct contact with the New World. In fact, most American species of plants and animals did not find a place in European kitchens until well over a century or two after 1492. At least they are not recorded in cookbooks, which were mostly meant for the wealthiest people in society. There is some evidence, however, that poorer people made use of the new plants shortly after their arrival. Botanical and dietary sources sometimes suggest that only out of dire necessity would one consume tomatoes or corn, which eventually served as cattle fodder throughout southern Europe but was also dried and ground and eaten as polenta. In some regions where corn became a staple, the nutritional deficiency called pellagra resulted because the grains were not soaked in lye or ashes, a process called nixtamalization, common in Mexico and important for making vitamins digestible. In any case, the

association of maize with poverty remained a strong one.

The first recipes including tomatoes and chili peppers appear in Spanish-ruled Naples at the very end of the seventeenth century in the cookbook of Antonio Latini, who offers what is essentially a tomato salsa. They also appear in various stews as a flavoring agent. Cooked tomato sauces did not appear in cookbooks, such as Vincenzo Corrado's, until the eighteenth century and were not paired with pasta until the nineteenth century.

Potatoes, New World beans, and squash also had a major impact on Mediterranean cuisine. The former were cooked into casseroles or dumplings called gnocchi; the latter were cooked in countless ways, exactly as Old World beans and gourds had been.

Despite these new ingredients, the foundations of Mediterranean cuisine remain the same as they were in ancient times: bread made of wheat, olive oil, wine, cheese, and native species of fish and cattle.

—Ken Albala

There was no exchange quite so momentous, however, as that occurring after 1492 when the Eurasian and African continents were for the first time in history linked to the Americas. Not only were European crops such as wheat and animals like pigs and cattle transported to the New World, but many New World species were brought to the Old World.

These new species first arrived in Spain and southern Europe on the boats of the earliest explorers. Initially, foods such as tomatoes, corn, yucca, and chili peppers gained interest only as botanical curiosities. Most Europeans avoided them as food, especially those plants with well-known poisonous relatives, like tomatoes in the *Solanaceae* family. Only those plants and animals that resembled familiar European species and could be used in a familiar culinary context were readily adopted. New World species of beans, those now classified as *Phaseolus*, were planted in the mid-sixteenth century as were squashes, which reminded people of Old World gourds in the *Lagenaria* family. These older foods were almost completely displaced

by zucchini and pumpkins. Turkeys, resembling familiar birds such as peacocks and pheasants, were also enthusiastically eaten by sixteenth-century diners. Guinea pigs also enjoyed a fleeting popularity. Corn gradually replaced the millet-based polenta or porridge common in Spain and northern Italy and elsewhere in the former Roman empire, such as Romania. It took many more years for tomatoes and, later, potatoes to become common foods in Europe.

The long-range consequences of these foods include increased food production, particularly on what was marginal land, and consequently dramatic growth of the European population. While many factors were ultimately responsible for the steady demographic increase after the sixteenth century, the new easily grown crops from the New World, which yielded a dependable supply of food, certainly played a role.

Explorers were also interested in finding spices and drugs, and they long believed that the New World would provide a direct passage to Asia and the profitable spice trade. Eventually they did find plants that they believed would be

useful in pharmacy, among them sassafras, sarsaparilla, and guaiac or Jesuits bark. Many of these were later adopted for purely recreational purposes or found a place as flavoring agents rather than medicines. Chocolate is the best known of these plants, but even tobacco was first used both medicinally and for pleasure. Among spices, only vanilla, and to a lesser extent allspice, became widely used in the Mediterranean.

While New World foods gained a mixed reputation in the Christian western Mediterranean, the predominantly Muslim eastern Mediterranean adopted them much quicker and more enthusiastically. This may have had something to do with a hotter and more arid climate, closer to that of Mexico. But this cannot explain why some items spread rapidly outside the Mediterranean basin. Chili peppers, for example, were grown and widely used in Hungary long before they were in western Europe. Asians adopted them even quicker.

Plants and animals were not the only creatures involved in the transatlantic exchange. Germs—viruses and bacteria—also made the trip, usually within the bodies of explorers themselves. While there is little doubt that diseases such as smallpox and measles, exported from Europe, devastated American populations, there is still considerable debate over which diseases were imported from America. In the sixteenth century syphilis appeared to be a new disease spread by sailors who had been to the West Indies. Its virulence suggested that it was relatively uncommon, though its exact origin is still in doubt.

The exchange of species from the New World to the Mediterranean would be merely one link in the chain of what would eventually become a truly global economy in which plants and animals are regularly exchanged from every continent.

The Columbian Exchange and Northern Europe

The pattern of exchange between the Americas and Northern Europe following 1492 was somewhat different than that experienced by the Mediterranean. There were early voyages to North America sponsored by the English and French beginning only a few years after Columbus, led by John Cabot and later Jacques Cartier. The majority of expeditions, however, took place long after Spanish settlement. Northern Europeans also focused more on what is today Canada, the United States, and the Caribbean, and successful settlements were not founded until the early seventeenth century in places such as Jamestown, Quebec, and New Amsterdam. By then, it is true that beaver pelts were regularly shipped to France to make fashionable hats, cod was being fished from the grand banks of Newfoundland down the coast of New England, and tobacco plantations would soon be exporting large quantities back to northern Europe, but these remained items of export and had no significant impact on the ecology of Northern Europe, though they naturally had a great impact on the Atlantic economy and on North American ecosystems.

Of equal importance is the fact that few colonists returned to Europe with the intention of transplanting native species. Normally they were more interested in exploiting local resources and exporting them or even importing Old World plants to be grown on colonial plantations using slave labor, as was the case with cotton and sugar.

The exchange of plants and animals indigenous to the Americas was thus far less dramatic than with southern Europe. This is partly because North America offered fewer species and few that could be viably grown in northern Europe, but it may also be related to a greater culinary conservatism among northern Europeans. Though corn, squashes, and beans were cultivated extensively by American Indians and colonists, few of these were grown in

➤ NEW WORLD FOODS IN EUROPE— TOMATO AND POTATO

The development of cuisine in northern Europe betrays little evidence of the Columbian Exchange immediately after 1492. It was not until a century later that Shakespeare mentioned potatoes (in *The Merry Wives of Windsor*), by which he meant sweet potatoes. These sweet potatoes made their way into English cookbooks in the course of the seventeenth century but never became a major article of food. It was only the regular potato, from Peru, in the course of the eighteenth century that had a dramatic impact on the European diet, after conscious promotion by figures such as Parmentier in France and Frederick the Great in Prussia. In the long term, potatoes found a prominent place in every northern European cuisine, from the Irish stew to Scandinavian potato salads to soups in eastern Europe, not to forget the french fry. Most other New World plants were scarcely noticed in northern Europe, at least until the twentieth century and with the advent of refrigerated transport. The only New World plant that Europeans have adopted with enthusiasm perhaps even rivaling that of its place of origin is chocolate. But this is not, of course, grown in Europe.

—Ken Albala

northern Europe. Interestingly, it was only the green bean that became so acclimated as to be called the French bean. Sweet potatoes, called potatoes of Virginia, were known in England in the sixteenth century and, interestingly, had a reputation as an aphrodisiac. It was not until much later, though, that regular potatoes were grown there and particularly in Ireland. Only in the eighteenth century were potatoes grown in France and Germany, but their impact thereafter was stupendous, particularly among the poverty stricken, who came to depend on them for the bulk of their calories. This would have disastrous results in the mid-nineteenth century in Ireland, Belgium, and elsewhere when blight hit the potato crop and caused widespread famine. This led to a massive migration of people from Ireland to North America.

Other New World plants were less enthusiastically adopted. Tomatoes and peppers, which

do not grow very well in colder climates, found practically no place in the northern European diet until the twentieth century. The same is true of corn, which was normally used to feed animals. The sunflower, native to North America, had some impact. The roots of one species, the Jerusalem artichoke or topinambour, enjoyed a brief vogue, and much later the seeds and oil became an important crop. American species of strawberries replaced smaller European varieties. Other indigenous North American products such as pecans, maple syrup, and cranberries were consumed only in the colonies.

By and large and with the exception of the potato, which is now universally consumed as a basic staple ranking only behind bread, it is safe to say that northern Europe was one of the places on earth least affected by the Columbian Exchange. There were no comparable large-scale invasions of livestock, pathogens, weeds, or people for that matter, certainly nothing like what traveled in the other direction. The exchange, although certainly not one-sided, was nonetheless unequal. Regarding human populations, the first Native Americans brought to Europe for display quickly succumbed to disease. Today there is practically no Native American population in northern Europe.

The Columbian Exchange and North America

Separated for millennia from the Eurasian continent, the flora and fauna of the Americas evolved in accord with prevailing local conditions. The mammals, birds, lizards, snakes, trees, bushes, and grasses that took root corresponded to similar plants and animals in Europe but nevertheless remained distinct species. It was this unique ecosystem that Europeans confronted when they first began exploring North America in the fifteenth century.

European impact on North American ecology was profound. Diseases brought from the Old World to the Americas devastated local human populations. Waves of European settlers and the economic exploitation of the New World's resources also slowly reshaped the land, as well as its flora, and fauna. Thus, to give one example, wealthy, urban Europeans liked hats and beaver fur—smooth, water repellent, and consisting of hundreds of small barbs—suited the hatmakers' needs perfectly. By 1600, beaver skins had become the hatmakers' preferred material. Correctly assuming that Native Americans knew how to locate and capture beavers, the Europeans began offering to trade for beaver hides. This link to the European market had disastrous consequences for the beavers who quickly disappeared from the coastal regions from the St. Lawrence River south. The ecological diversity the beaver ponds created and their role in holding back floodwater was lost along with the beavers.

While Europe was a land of settled agriculture and land ownership, where the Pilgrims came ashore—far from their land grant—land abounded and had no owners, at least not in the European sense. The Pilgrims' first official act was to draw up a "compact" to create a government, which then proceeded to allocate land to the settlers. Once on land designated as theirs, families built homes, cleared fields, and put in vegetable gardens. Within a few years, more animals began to arrive—cows (it took three years before the first bull and three heifers arrived), oxen, pigs, sheep, goats, chickens, and horses. With land aplenty and little time to gather food for themselves, let alone for their animals, these early settlers let their livestock roam free. The pigs flourished the most in this new environment. Left on their own, they roamed the forests, feasting on acorns, wild tubers, and other roots. Cows and horses were also left to wander and scavenge food where they could. As they were more vulnerable to predators, sheep and goats were kept closer to home. To keep the cows, horses, and pigs from tramping down or digging up plantings, fields were fenced. Pigs dug up the forest, while cows and horses trampled the ground, compacting it in the process. As herding animals from a wet climate, they gathered,

usually by streambeds, eating the native grasses until nothing was left but bare ground, compacted but still subject to erosion.

As their animals began to change the land, the settlers began to alter the landscape by importing flora from home; other plant species arrived on their own. The colonists wanted flour, particularly wheat or rye flour, for their bread and for market. Wheat and rye flour sold in the markets of Europe, so that is what the early settlers assumed they would have to grow to be commercially successful in this new world. Wheat grew in cleared fields. Granted land possession by their new government, the early settlers imported oxen to pull tree stumps from their new fields. They also built wooden flats or sleds on which they loaded the stones that littered the ground. With the aid of oxen, they transported these stones to the fields' edges and used them to construct what would become the classic New England stone walls. With the fields cleared, the colonists planted wheat and rye.

Closer to their homes they planted vegetables, and in the lowlands they cut down the maples and birches and planted fruit trees brought from home—first apple trees of many varieties, then pear, oranges, peaches, plums, and cherries. But as they planted the seeds they painstakingly brought or had sent from home, they also planted what they had not intended. Weeds also arrived as stowaways in the bags of seeds, in animal feed, and clinging to clothing, buckets, and barrels. Soon, around each English settlement, there were not only fields of wheat and rye, but also patches of dandelions, chickweeds, bloodworts, and nightshades. Noticing the prevalence of these new and exotic plants where the Europeans settled, the Native Americans labeled them "Englishman's Foot." These invading plants were well adapted to surviving in disturbed ecosystems. Broadleaves, like dandelions, thrived in open, plowed fields and overgrazed pastures. As European animals ate the existing native grasses such as broomstraw, wild rye, or marsh grass (spartinas), the invading weeds moved in. Ragweed, an indigenous plant held in check by forest cover, took advantage of the opening of fields and spread rapidly. Other native grasses and plants fared poorly under the impact of European animals.

As the native flora were eaten and trampled, Old World grasses, having evolved along with domesticated animals and capable of quick rooting and seeding in tough, trampled ground, spread in their stead. When the Europeans first built their settlements, open ground was scarce and confined mostly to abandoned Indian fields and meadows. When domestic animals began arriving, they were turned out onto these fields and meadows. The settlers considered the indigenous grasses inferior to those back home. As the animals overgrazed these spaces, newly imported grasses, such as bluegrass and white clover, grew up. Initially these plants arose as volunteers, having come over in animal fodder. Although the appearance of the “better” haying and grazing grasses pleased the European settlers, their animals’ ever-increasing demand for food could not be satisfied by these “volunteers.” As a result, farmers were soon clearing more pastureland to sow fields with “English hay.” But the demand for animal food increased too rapidly for the farmers to keep pace by clearing land for pasture and haying. This forced most settlements to remain close to areas with large tidal marshes or extensive meadow wetlands where fodder could be harvested, even if by necessity from “inferior” native grasses.

Roaming domesticated animals deprived farmers’ fields of precious nutrients. As Europeans cleared stones and stumps from their fields and began planting, they faced the problem of declining productivity as each year more nutrients were taken up in the planted grain and then removed from the field. Some early colonists solved this problem by abandoning fields and letting them lie fallow for several years before returning the fields to crop production. Practicing a bush fallow strategy of letting their fields lie fallow for six or seven years, farmers were virtually guaranteed to face a field rife with bushes, brambles, and a tangle of roots at the end of the fallow period. These fields could not be plowed or dug by hand. Animal power was necessary to pull through the entangled roots. To abandon a field and let it sit idle for six or seven years required that a farmer own a large parcel of land. But because farmers ultimately passed property on to their children, there was soon too little land to let so much of it sit fallow.

Animal manure offered a way out of the land scarcity dilemma. Loaded with nitrates, animal wastes could restore fields. But as long as the animals wandered freely, grazing wherever they found food, their wastes were scattered throughout the countryside. Because edible grasses flourished by waterways, meandering livestock often deposited their wastes alongside rivers and streams. The wastes and the nutrients contained within them would then typically be washed downstream with the next rain. And even if the wastes were not washed away, the farmer could scarcely tramp around the countryside collecting cow, horse, or oxen dung.

Containing animals in fenced pastures more successfully contained their wastes. After harvesting the grain from fields with declining productivity, farmers would seed them with “English hay,” bluegrass, or white clover. Once the grasses came in, animals could be turned out on the fields, and their manure would add nutrients to the soil. With such a plan, rather than having to wait six or seven years, farmers could replant their fields with grain crops after just two or three years. But this strategy also involved more work. Fences had to be well built to make sure the animals did not wander off. Animals confined to pasture fields ate away grass cover. They also trampled and compacted the earth, which made it more difficult for grasses to reseed or resprout. Thus, farmers increasingly needed to plow and reseed or face the problem of open dirt subject to erosion. The compacted ground was also more difficult to plow and demanded the aid of draft animals.

An imported economy that included ranching in the south and southwest introduced other problems. Spanish settlements along the Rio Grande imported cattle into what is now Texas sometime after 1659, including herds of Longhorns that would spread slowly eastward across the state. It was in Florida that the range animal had its greatest impact on the southern environment, however, as not all lands of the interior were savannas or treeless plains as was the case in many parts of Texas and Oklahoma. In Florida, fire was also likely used by ranchers to produce larger areas of grassy vegetation, although reputable historical evidence for the practice during the early colonial period is relatively

sparse. Even if fire was not used regularly by ranchers, the cattle would have themselves created greater expanses of treeless territory as well as helped maintain that which had already been deforested earlier by Spanish colonists or native Indians. When herds of cattle were ranged in forested areas, they would have eaten saplings and shrubs, creating a more park-like effect than had ever existed before in those areas. Thus, over time, Spanish herding practices—which also employed Indian and African labor—would have most likely created “a decrease in the diversity of hardwood forests,” and at the same time caused a noticeable increase “in the area of natural or artificial grasslands.”

Domesticated animals provided the family with an important source of protein but in the early years of settlement, when domesticated animals were in short supply, European settlers obtained protein the same way Native Americans did—they hunted. And they hunted the same animals: deer, moose, ducks, geese, pigeons, and ground fowl such as turkey and grouse. They hunted with such intensity that within two generations deer and moose disappeared from settled areas. Turkey and other ground fowl soon followed. Passenger pigeons were so prolific that they persisted for another hundred years before being eliminated from the area. The passenger pigeon population may have increased in the early seventeenth century as the deaths of Native Americans that had set up their villages in river valleys opened up new areas for the pigeons to roost. The appearance of huge flocks of passenger pigeons that darkened the skies of the Northeast for days were not yearly occurrences. The massive flocks would arrive irregularly, usually once every seven or eight years, in what were known as “pigeon years.” Pigeon populations may have held out longer than those of deer and moose, but declining numbers of game soon became a reality, forcing families to depend even more upon animals they raised.

European settlers had a lasting impact on the interaction between humans and nature. In northern Florida this meant that by the mid-seventeenth century, Apalachee and Timucuan Indians would be routinely cultivating European fruits and vegetables and even herding Spanish cattle. And even for those Indians who would

➤ EUROPEAN FOOD IN THE AMERICAS

American cuisine provides the most tangible evidence of the global transfer of foods after 1492. Each wave of European settlers carried over the plants and animals they knew and favored, but they also integrated native species into traditional foodways in ways unique to North America. In Canada, French settlers introduced pigs, which they cured into hams, and yellow peas and wheat, which they used for bread and pancakes. But they flavored customary foods with local maple syrup and added native wild rice as a sidedish. The Spanish settlers brought cattle for familiar beef dishes but combined local tomatoes and chilies and wrapped them in Eurasian wheat flour tortillas. Africans brought rice to the Carolinas along with crops such as okra. Consequently, regional cuisines in North America contain both New World and Old World ingredients. For example, in Virginia, Brunswick stew traditionally contained local squirrel or chicken along with tomatoes and corn but also European onions and a slab of salt pork. In New England, a simmering pot may have contained Old World beef pot roast, carrots, and onions as well as New World potatoes. The combination of species from different continents became second nature across North America. There is perhaps no better example of this tendency than the Creole and Cajun cooking of Louisiana. One will find French andouille sausages and boudins, French techniques such as a roux of flour and oil or butter, and celery and onions combined with African okra or native file powder (ground sassafras leaves), Asian rice or chicken, and chili peppers and tomatoes from Mexico.

—Ken Albala

continue growing traditional crops alongside the new arrivals, increased demands on the local ecosystem required adopting a much more intensive slash-and-burn agriculture. To more rapidly create fertile fields for cultivation, missionized Indians would first girdle large trees on forested tracts, burn them to release important nutrients, and then repeat the process again elsewhere after the soil was exhausted. According to environmental historian James Miller, the practice made it necessary for entire mission villages to relocate to areas that had not been

cleared, producing, over time, a pattern of “old fields” recognizable to British surveyors a century later.

By the mid-seventeenth century, the greatest landscape change occurred as the direct result of tobacco growing, which started on a grand scale after 1620, the year more than 60,000 pounds (27,000 kilograms) of the cured leaf were shipped directly to London. Just seven years later, 500,000 pounds (227,000 kilograms) of the cured weed were exported from Virginia, to ports in both Europe and the West Indies. The lure of growing tobacco remained irresistible to the colonists even though growing the plant ultimately proved detrimental to the thin topsoils of the Atlantic Coast, wearing them out in four or five years. Even when corn was grown on worn-out tobacco fields, the yields were not generally sufficient to stop the forest clearance process and the constant movement of settlers from old to new ground. Although not all of the timber cutting can be directly attributed to tobacco cultivation, by the end of the seventeenth century, nearly a half-million acres (over 200,000 hectares) were deforested in the Virginia colonies alone, and historian Kirkpatrick Sale noted that such species as “white oak, black walnut, and white cedar ... were effectively exterminated.” The residual ecological effects of timber cutting were no less severe, including the deterioration of beaver dams and ponds, the lowering of water tables, increased floods and topsoil runoff, siltation, and stream bank erosion. Tobacco cultivation also pushed the English even farther inland, where they could engage in other economic pursuits, including trapping fur animals for peltry. Having exhausted the supply of beaver in New England by the mid-1620s, enterprising fur-trappers now had their sights on the streams and forests west of the Chesapeake Bay, habitat that still contained large numbers of beaver, mink, and muskrat.

Captivity Narratives—German Settlers among American Indians

Throughout the colonial period of North American history, white settlers’ encroachments on American Indian lands brought frequent conflicts. For European settlers, the possibility of kidnapping and captivity was an intensely feared possibility. Those who experienced captivity contributed to the emergence of a literary genre that typified colonial American history: the captivity narrative.

Taking captives had long been a customary technique of Native American warfare. Indians seized captives for various reasons: to seek revenge, to obtain ransom, or to replace relatives killed in intertribal or colonial wars or who had died of European diseases. The actual number of Indian captives is speculative because most individual fates remained unknown. Hundreds are known to have died en route or in captivity, many were sold or ransomed to the French or English, some converted to Catholicism and stayed in French Canada, and some were adopted, assimilated into their captors’ culture, and refused to return. Only a few of those who came back left accounts of their captivity.

Those ex-captives who either penned their experiences themselves or, more frequently, dictated them to others created the genre of the American Indian captivity narrative in American literature. Mary Rowlandson’s *Sovereignty and Goodness of God* (1682) is considered the first captivity narrative and a landmark in early American literature. Tales of bloody encounters with Indians enjoyed enormous popularity and were widely read on both sides of the Atlantic.

Most captives were of Anglo-Saxon origin, and most narratives were recorded and published in English. However, Indians abducted non-English speakers as well, and there are many captivity texts in languages other than English. Several narratives in German and English as well as many historical documents reveal that German settlers were among those snatched by Indians.

The first German in Indian captivity was presumably Hans Staden from Homberg in Hesse. In the mid-sixteenth century he sailed to the coast of Brazil, where he was caught by the Tuppin Imba, a tribe supposedly practicing cannibalism. Staden managed to survive for months among his captors before escaping to freedom. His account—*Wahrhaftige Historia und Beschreibung einer Landschaft der wilden nacketen grimigen Menschenfresserleuten, in der Neuen Welt Amerika gelegen (True History and Description of a Country of Wild, Naked, Terrible Man-eaters Who Dwell in the New World Called America)*—was first published in 1557 in Marburg, Germany. It became a best-seller and was reissued in many languages, including English, French, Portuguese, and Dutch. *Wahrhaftige Historia* probably represents the earliest Indian captivity narrative, appearing 125 years before Rowlandson's and anticipating many of the features of the captivity genre. It also bears similarities to John Smith's account of his rescue by Pocahontas in his *General History of Virginia, New England, and the Summer Isles* (1624), the most famous captive story of an English man. Like Smith, Staden presents himself in the heroic mode, adventuresome and full of bravado.

Tales by or about Germans in Indian captivity became more frequent during the eighteenth century. A famous story is that of the Leininger family, who had migrated from Reutlingen in Württemberg in the 1740s and settled in Pennsylvania. During the Penn's Creek Massacre of 1755, Allegheny Indians raided the family homestead and murdered the father and one son. While the mother and another son were absent at the time of the attack, the daughters, Barbara and Regina, 10 and 12 years old, were carried away into the wilderness. Barbara and another captive, Maria Le Roy, escaped in 1759. The account of their captivity and daring getaway was

New England colonist Mary Rowlandson was taken captive by Native Americans in 1676, during King Phillip's War. She was the first to publish an account of her experience, in 1682. The genre soon became known as "captivity narrative." (North Wind Picture Archives)

published, simultaneously in German and English, in the year of their escape (*Die Erzählungen von Maria le Roy und Barbara Leininger, Welche vierthalb Jahr unter den Indianern gefangen gewesen, und am 6ten May in dieser Stadt glücklich angekommen*, or *The Narrative of Marie Le Roy and Barbara Leininger, for Three Years Captives among the Indians*). Regina, separated from Barbara, remained with the Indians for nine years. She was among the redeemed captives whom Colonel Henry Bouquet forced the Indians to relinquish in 1764. By the time she gained release, Regina was an adult who had forgotten her mother tongue and abandoned European ways, and so it was likely that her own relatives would not recognize her. But mother and daughter recognized each other through the words of a German hymn. Evolving from an eighteenth-century German exemplum of Lutheran devotion in times of affliction, Regina's story has been told and retold, many versions mingling fact with fiction. From Heinrich Melchior Mühlentberg's initial account, recorded in his diary of 1765 and published in *Hallesche Nachrichten* in 1769 to a nineteenth-century American tract for Lutheran Sunday schools (Reuben Weiser, *Regina, the German Captive*, 1860) to a twentieth-century

► HERMAN LEHMANN'S STORY

Like many other ex-captives, Herman Lehmann had considerable difficulty reintegrating into white society. The following incident from Herman's life, narrated in *Nine Years among the Indians*, is symptomatic of the emotional turmoil many so-called white Indians faced after being returned to their culture of origin:

"He had forgotten his mother tongue, and could not speak English. He sought every occasion to shun the company of others, and when assigned to a clean feather bed in which to sleep, he refused, preferring to sleep on the ground with only a blanket for a covering. . . . It was a difficult matter to induce him to wear clothing, and oftentimes he would doff the suit furnished him, paint himself, and with leggings, breech-clout and feathers, appear among the hotel guests in all the barbaric panoply of a Comanche warrior.

A few weeks after his return, a protracted meeting was being held under a brush arbor in Loyal Valley. Herman viewed the proceedings from a respectable distance, and his amazement was extreme. He finally concluded the whites were having a rain dance, and one day at the 11 o'clock service, when religious feeling became intense and singing and shouting was at its height, Herman dashed into the altar with his war club, and engaged in a war dance that had a startling effect. His brothers seized him and led him away, and the service closed without the benediction."

novel for adolescents about cultures in conflict (Sally Keehn, *I Am Regina*, 1991), the story has crossed the Atlantic back and forth.

Another example of the colonial American captivity narrative was "Erzählung Eines unter den Indianern gewesener Gefangenen" ("Narrative of an Indian Captive"), published in the *Neu-eingerichteter Americanischer Geschichts- und Haus-Calender (New American Historical and Domestic Almanac)* in 1762. The narrative depicts the story of Abraham Urssenbacher, who had migrated to Heidelberg Township, Pennsylvania, in 1759 and was serving as a soldier when Heidelberg was attacked. He was captured but managed to escape; his wife, infant daughter, and other relatives were slaughtered in the attack, however. His narrative, written in the first person, focuses on the appalling details of his survival alone in the wilderness.

In 1809 *Merkwürdige und interessante Lebensgeschichte der Frau von Wallville, welche vier Jahre lang an einen Irokesen verheyrathet war (The Remarkable and Interesting Life Story of Mrs. von Wallville, Who Was Married to an Iroquois for Four Years)* was published. The book supposedly presents the first-person

narrative of a certain Maria von Walwille, who recounts her captivity among the Iroquois, escape to freedom, and later marriage to Count Wallville. And although widely published and retold, it is probably fictitious, based on a tale that had appeared in 1799.

Among the many children who were captured on the Texas frontier during the nineteenth century, three German Texans stand out: Rudolph Fischer (1852–1941), Adolph Korn (1859–1900), and Herman Lehmann (1859–1932), all remaining to live with their American Indian captors. Fischer, captured in 1865, spent his entire adult life with the Indians. He became a full-fledged Comanche and was renamed Asewaynah. Korn was captured in 1870 near Castell and recovered in 1872. Not being able to readapt, he spent the rest of his life as an outcast. Lehmann was nabbed by Mescalero Apaches when he was 11 years old. He gained warrior status and lived with the Plains Indians until Quannah Parker (Comanche chief and son of Cynthia Ann Parker, herself captured by Indians in 1835 and later married to an Indian) convinced him to return to his white relatives. He did so grudgingly in 1878 and readapted with much difficulty

to white society. Two different versions of his narrative were published in 1899 (*Indianology*, written down by Jonathan H. Jones) and 1927 (*Nine Years among the Indians*, written down by J. Marvin Hunter).

Migration and Travel

If one were forced to choose a catchphrase that would express the defining characteristics of this era, the period 1450 through 1770, it would be “the world that travel and migration built.” For the first time in history, the people of every continent came into contact with each other. Explorers, traders, missionaries, imperialists, and refugees built webs across oceans, setting into motion forces that culminated in widespread social, economic, and political reorganization. The laws of unintended consequences were in full operation: millions died from exposure to new pathogens, but millions of other people survived because of new highly nutritious food sources becoming available. One side of the Eurasian landmass gained unimaginable wealth in silver and gold, managing to send itself into a spiral of inflation and economic instability. Wily African traders found a means through which to gain wealth while depleting the resources of their competitors and sent their lands into spirals of exploitation and devastation. The escalating consequences of travel and migrations forced societies around the world to adjust to a new reality.

All of the travel and migration of the time had an aim, whether voyagers were pursuing personal fortune, serving a monarch, serving God, trying to escape persecution, or had been banished by courts or monarchs. A push-pull dynamic motivates changes in human travel and migratory patterns; that is, travel and migration generally have an aim. In order to understand this dynamic, the essential questions of what happened and why it happened require some rather arbitrary decisions. One is always tempted to start with the “Big Bang” and work forward. That would assuredly lose many readers, so we will begin with a brief glance at the Black Death and the adverse weather conditions known as the Little Ice Age, both key events that pushed desperate people into motion.

These massive folk movements began in the mid-fourteenth century as the Black Death spread along trade routes protected by the Mongol empires of the thirteenth and fourteenth centuries. The high death rates, sometimes as great as 60 to 70 percent of affected populations, disrupted the economic and political organization of societies across the Eurasian landmass from China to the British Isles. By 1500 in England alone, the plague had destroyed about 1,300 villages, their populations either dead or disbursed. The migrations set in motion by the plague were often internal migrations wherein people tried to relocate to areas not stricken, but many also drifted into hitherto sparsely populated frontier zones. The existing economic system of Europe, based on agricultural peasants affiliated with a feudal lord, eroded as peasants took their chances and moved or negotiated for better terms. The plague reappeared periodically until the late seventeenth century. Before the

demographic recovery was under way, the Northern Hemisphere experienced an extended period of unstable and abnormally cold weather known as the Little Ice Age, which began about 1300, intensified around 1600, and ended by 1850 but not before making George Washington and his troops miserable at Valley Forge in the winter of 1777–1778. The Little Ice Age was not a gradual or consistent pattern of weather change, but extremely cold winters and dry springs were frequent. In many of these years, subsistence farming was impossible across the northern reaches of Europe and Asia, destabilizing political and economic organization across the zone and inspiring people to migrate to new lands and even into hitherto unknown territories, such as the Americas. The harsh winters were also evident in the records of the European immigrants to North America, where the combination of adverse weather and the introduction of new pathogens killed millions of Native Americans. In *The Little Ice Age* (2000), Brian Fagan writes of cypress tree rings that attest to severe droughts in Virginia during 1587–1589 and of the hardships faced by settlements in Spanish Florida as well as along the eastern seaboard of New England. At Jamestown, for instance, the colonists faced the driest period in more than seven centuries. Of the 104 colonists who arrived in 1607, only 38 survived a year.

The harsh winters and dry summers lowered production and drove people of all stations to seek critical resources elsewhere. The winters in the 1590s, the 1620s through the 1650s, and the 1690s were particularly harsh. A mere 1 degree Centigrade decrease in average summer temperature shortens the growing season for crops by three or four weeks, a disastrous drop for economies based on subsistence agriculture.

In some areas the decline in agriculture was catastrophic; for instance, tithe records for Hungary indicate that yields fell by 72 percent between 1570 and 1770. Famines occurred throughout Eurasia. Competition for resources frequently led to invasions, civil wars, and rebellions during the seventeenth century across Eurasia from Japan and China through Russia,

Bohemia, Germany, France, Italy, Portugal, Sweden, Holland, Scotland, Ireland, and England. Existing social, cultural, and economic structures were not equipped to deal with the ongoing crises. The Ming dynasty began facing intensified rebellions and sorties by northern nomads by the late sixteenth century, beginning the slow decline that led to the end of the Ming, the last native Chinese dynasty. The harsh weather pushed the northern nomads into traditional Chinese territories even as the Han Chinese farmers pressed into the regions of Mongolia, Turkistan, Tibet, and southeastern Siberia.

East Asian societies, particularly China, searched inward for resources, but these economic crises propelled Europeans into a search for access to new sources of material wealth, including both necessities and luxuries. The quest for entry into thriving Asian markets led to the discovery of the New World, bringing both unimaginable wealth and incomprehensible misery. Pathogens, belief systems, technology,

In some areas the decline in agriculture was catastrophic; for instance, tithe records for Hungary indicate that yields fell by 72 percent between 1570 and 1770. Famines occurred throughout Eurasia.

wealth, and resources crossed landmasses and oceans. Explorers and soldiers led the way, with missionaries and traders in their wake. Sub-Saharan Africa and the Americas did not suffer the direct impact of the plague, but the movements that were set into motion eventually disrupted them as much as (and perhaps more than) the areas that had been set into motion by plague and weather.

China and western Europe recovered first from the social and economic upheavals of the Black Death, and both set about attempting to develop or reinstate trade networks. China launched a large naval presence into the seas around East and South Asia in 1405 but abandoned its naval initiatives in 1433 for reasons that are not entirely clear. One suspects that the northern pastoralists set into motion by the deteriorating weather conditions inspired the Chinese to focus their treasure and attention on protecting their northern border. Throughout its existence China had experienced raids and even conquering armies from the north. The Chinese had never had reason to be unduly concerned about attacks from the seas. When one of the northern peoples, the Manchus, established the Qing dynasty in 1644, Ming sympathizers and supporters fled to the south. Throughout their two and a half centuries of rule, the Qing remained suspicious that strangers attempting to enter China from the south were associated somehow with the Ming. Among European observers, China's attention to securing borders caused a wide and erroneous perception of a static land. The Chinese were in fact as expansionistic as the Europeans; this has been largely overlooked because China embarked on a land-based expansion rather than the sea-based empires of the European maritime states. The Qianlong emperor (1711–1799) doubled the size of China, creating room for massive internal migrations.

By the time the Chinese abandoned their maritime explorations in 1433, Europeans had already embarked on their own maritime adventures. We historians sometimes present the period as the “European Age of Exploration and Discovery,” inadvertently implying that it was a sudden series of events. Actually, fishermen along the edges of both the Atlantic and the Mediterranean had been exploring the seas around them for centuries, developing sturdy little ships and a cadre of experienced sailors. In the fifteenth century a Portuguese prince, Henrique (often called Henry the Navigator), sponsored efforts to improve the naval technology and encouraged an aggressive naval presence. Portuguese forces seized the Moroccan city of Ceuta, which guarded the Strait of Gibraltar, soon conquering islands off the African coast, where they joined with Italian investors to develop extremely profitable sugar plantations, setting a precedent of colonization emulated by the other west Europeans who followed. Success breeds success, and further voyages followed. The Portuguese were also the first to fight their way into the Indian Ocean trade. During these travels they saw opportunities for both economic and spiritual ventures, transporting merchants as well as missionaries. They also launched the first large-scale forced migration of the early modern world. By the mid-fifteenth century the Portuguese had transported thousands of African slaves to work on the sugar plantations, setting into motion the globe's most tragic forced

migrations. Asia's wealth also drew the Portuguese, who dominated the sea trade during the sixteenth century. Bartolomeu Diaz rounded the Horn of Africa. Portuguese monarchs also funded the explorations of a Genoese mariner, Christopher Columbus, who inadvertently brought the Americas into the global network. The explorer Vasco da Gama sailed southward around Africa, learned to handle monsoon winds, and made his way to India. Their successes drew the northwestern Europeans. Spanish, Dutch, English, and French adventurers followed, inaugurating the first era of sustained contact involving the Americas, Asia, Africa, and Europe. The mapping of the world's oceans was essentially completed when Captain James Cook explored the shores of Australia in 1770. These explorers paved the way for merchants and colonists and for the efforts of missionaries to save the souls of pagans.

The missionaries who traveled to new lands were arguably the most prominent observers and cultural transmitters between societies. Like Buddhism and Islam, Christianity is a missionary religion, and this was an age of dramatic and dynamic Christian expansion. Others were also proselytizing throughout the age, although their activities were not as intense during this time. Sufi missionaries continued their efforts in lands of the Ottoman empire and eastward, and Buddhist missionaries continued circulating throughout Asia. The misfortunes of the plague and weather caused many societies to search for meaning,

The missionaries who traveled to new lands were arguably the most prominent observers and cultural transmitters between societies. Like Buddhism and Islam, Christianity is a missionary religion, and this was an age of dramatic and dynamic Christian expansion.

a divine hand perhaps sending a message. Many Chinese began to suspect that the Ming dynasty had lost the Mandate of Heaven.

In Christian Europe people searched for meaning, suspecting punishment for unnamed sins and questioning the efficacy of their religion's hierarchy. As he searched his own soul for sin, the priest Martin Luther suspected that others shared his guilt, and he released his 95 "theses" that announced his protest against the established church on October 31, 1517. Witchcraft accusations soared, reaching their height in England and France in 1587 and 1588. The resulting religious wars and intrastate violence not only acted as an impetus for proselytizing but also drove many dissenters to migrate. Dedicated Roman Catholics were as aware of problems in the Church as Luther had been. The efforts to reform the Church led to the formation of an assembly of high Church officials, called the Council of Trent, that met between 1543 and 1563. During this period the Society of Jesus (the Jesuits), led by Ignatius of Loyola, was formed. Ignatius was a military man, and the Jesuits practiced a military-type discipline. Their focus was twofold: education in Europe and missionary work in foreign lands. Most were remarkably intelligent, and many were great creative thinkers. They were by far the most highly educated men in Europe. Fourteen years of advanced education, spiritual development, and teaching experience were required before final vows. Rather than waiting passively for merchant transport, Jesuits launched Missions to India, Japan, China, any

place, in fact, where they could bring “salvation” to the troubled souls of the world. Although these dedicated priests went to China to “save” pagans, after associating with the court these proselytizers wound up becoming very Confucian in their own outlook. They were in constant contact with their brothers in Europe, the homebound Jesuits, who became the educators of aristocratic Europe. These Jesuit educators certainly played an active role in stimulating the vivid dialogue of the philosophes. By 1600 there were over 100 Jesuit schools including La Flèche, where Descartes was educated, and Louis le Grand, attended by Voltaire, Diderot, Helvetius, Malesherbes, and Choiseul, to name a few. Even Protestants such as John Locke avidly collected the letters and pamphlets sent home by the Jesuits in China. It can be argued that these Jesuit travelers to Asia, Africa, and the Americas forged the most powerful intelligence network in existence.

Nonetheless, the Jesuits were not alone in disseminating Christianity. The expansion of Christianity was not always peaceful. Two other orders of Catholics—the Franciscans and the Dominicans—were especially active. European conquerors in the Americas brought priests with them. Dominican priests arrived in Mexico by 1524; in fact, much of our current knowledge of Aztec, Mayan, and other indigenous societies comes from the priests’ records. And yet they destroyed temples and libraries, making it much more difficult to understand pre-Columbian peoples. The first bishop of Mexico claimed that the Franciscans had converted more than 1 million souls, yet the depth of the original indigenous converts’ commitment is very questionable, as was the means of conversion. The Spanish Requirement of 1513 required (hence the name) that failure of the Native Americans to convert was an act of war against both Spain and Christianity. When the Spanish arrived in the Philippines in 1565, they set about conquering coastal regions for use as a base. Despite strong resistance from Muslim communities, within a decade the Spanish controlled most of the region, pressuring prominent Filipinos to convert. By 1770, the end of this era, the Filipinos had become zealous Roman Catholics.

The Protestant Dutch and British were somewhat less diligent. In fact, the British East India Company, chartered in 1600 and ruling Bengal by the end of the era, actively prohibited missionary activity in areas under their control, believing (correctly it seems) that the presence of missionaries complicated business dealings. Russia also supported the activities of Eastern Orthodox missionaries in Siberia in the hopes of integrating Siberian and Arctic people into Russian society, but they were never as zealous as Roman Catholics or the Protestants who followed later.

In Russia, the emergence of the powerful Muscovite Rus led to the spread of eastern Slavs across the Eurasian plains. Grand Duke Ivan III (1462–1505) pushed Russian expansion south and west, Tsar Ivan IV (1530–1584) supported Russian expansion to the east, and Tsar Alexis (1645–1676) established Russian outposts on the Pacific Ocean littoral. This expansion was accompanied by the gradual migration of Russian traders to the vast expanse of Siberia. More important was the Russian government’s efforts to encourage southward movement of the Russian population (most of whom were serfs owned by noble

landlords), which displaced local nomadic tribes. Domestically, however, the Russian tsars pursued a different policy as they tried to restrict peasant mobility. Still, many Russian peasants risked their lives to flee from their masters to the southern borderlands and Siberia. This process particularly accelerated during the Time of Troubles (1598–1613), when natural disasters, political turmoil, and war forced tens of thousands to migrate. Once the stability was restored under the new Romanov dynasty, the Russian authorities restricted internal mobility. The legal code of 1649 put an end to legal migration by tying peasants to the land. Re-

stricted mobility had a profound impact on Russia, as it hindered the development of urban labor forces needed for industrialization and economic development.

The first European interaction in the Americas was between the Spanish and the peoples of the Caribbean. Their most deadly interaction was the spread of smallpox and other diseases. There was a dramatic reduction in population after 1518. Demographers have not firmly established the exact numbers, but there is some evi-

dence that as many as 90 percent of the peoples of the Americas died within the next century. When Europeans landed in the Americas, the pathogens they carried were more deadly than their military expertise. Disease raced ahead across the trade networks that existed throughout the Americas, devastating populations before the first European set foot on the land. One can only really understand the conquest of the Americas by the Spaniards, the Portuguese, and later the British and French by examining their activities in the context of the destabilization and depopulation that preceded the actual European settlers. This depopulation sent entrepreneurs in the New World on a search for inexpensive labor sources.

At the opening of this era in the year 1500, slavery existed throughout the world but was on a comparatively small scale. Africans constituted a minority in slave populations. By 1700, the largest slave populations were primarily African and located in the Americas. Portuguese, Spanish, Dutch, English, and French investors sought them in order to minimize the costs of production in the mines, plantations, and fields of colonies. Before the trade ended, approximately 12 million African people were forcibly transported; as many as 13.2 percent of slaves transported died during the crossing of the Atlantic. While nearly as many slaves were taken from Africa through the Indian Ocean littoral in the longer period from 800 to 1800, the transatlantic trade was much more intensive and devastating. As devastating to Africa and Africans as it was, the Africans fared better than the Native American slaves, who had no immunities to Old World pathogens. African's darker skins made it much more difficult for them to escape and blend into existing populations; some argue that it was here that modern racism was born. Many Europeans profited from the slave trade, but the escalating violence and competition for African slaves had scarred the countryside. The labor

The legal code of 1649 put an end to legal migration by tying peasants to the land. Restricted mobility had a profound impact on Russia, as it hindered the development of urban labor forces needed for industrialization and economic development.

imbalance (primarily young males were captured and sold) had a far-reaching impact, and the cross-societal animosity endured for centuries.

The ripple effect of these contacts and migrations continued; it is likely they are still shaping international relationships. At the opening of this era in the year 1500, Europeans were struggling to reform their economic and political structures. At the end of the era, the mid-eighteenth century, China was still the most powerful state on earth, but its decline was in progress. After Qianlong's death in 1799, it is doubtful that there was anything the Chinese could have done to maintain regional hegemony. By 1770, European investors and colonists had left a mark on every continent. Restive North American British colonists were preparing to rebel. The British were pushing the French out of the South Asian markets, and the British East India Company clearly dominated the South Asian and Chinese European trade. Restless Europeans had changed the world, and the world had also changed Europeans.

—Carolyn Neel and Monique Vallance

■ Introduction: First Encounters

From the late fifteenth century to the seventeenth century, the world was brought into an unprecedented unity. The advance guard of this process was the mostly European explorers who “discovered” new continents, societies, and oceanic trade routes. Although these explorers came from many European backgrounds—some of the most prominent in the first wave were Italians, like the Cabots who sailed for England and Columbus and Vespucci who sailed for Spain—five western European nations dominated exploration: Portugal and Spain in the first wave followed by France, England, and the Dutch Republic.

The motivations of the explorers were various, and the encounters between them and the peoples they encountered took many forms. Many of the Spanish explorers of the Americas are referred to as conquistadors (conquerors), and their encounters were driven by the desire to acquire wealth and territories for themselves and the Spanish Crown. Precious metals (gold and silver) were a particularly powerful motivation for many of the early explorers, and violence and even torture of natives continued as an appropriate way to acquire the metals. Native Americans were also kidnapped and brought back to Europe by explorers beginning with Columbus,

providing evidence of the strangeness of the new societies of the Americas, but they seldom lived long in Europe's hostile environment.

Outside the Americas, whose indigenous peoples possessed a number of disadvantages in relation to their invaders, explorers had to treat people with more respect, and conquest was only infrequently a possibility. (Even in the Americas, some societies were far more capable of resistance than others.) From the first Portuguese voyages down the coast of Africa that began the Age of Exploration, European explorers in Africa and Asia were often more concerned with establishing trade relations than with conquest. This required not the arrogance of the conquistador but a more deferential attitude, although violence, whether directed against indigenous people or European rivals, was always an available tool. Other explorations, such as the early English voyages in the North Atlantic, were about direct access to natural resources (cod in the English case). Much of the French exploration of Canada and the Russian exploration of Siberia was driven by the needs of the fur trade, and the natives were principally of interest for their knowledge of and access to fur-bearing animals. The Dutch in Indonesia were looking for access and control over spices, and

when they could they would coerce natives into growing and harvesting spices for Europe's ever-expanding appetite.

Contact with different cultures produced varying reactions in the explorers. Much of their response was conditioned by Christianity, which gave them a hostile attitude to all other religions, whether the "idolatry" of the Aztecs or the Islam practiced through much of the Indian Ocean. The crusader legacy made Islam particularly problematic, and the rivalry between the Muslim merchants who had previously controlled Indian Ocean trade and the Christian newcomers became particularly bitter. However, this did not preclude a more respectful attitude to powerful Muslim sovereigns such as the Safavid shah of Persia or the Great Mughals of India.

The contacted peoples in turn had different attitudes toward the Europeans. Many Native Americans were initially impressed with the advanced technology, including the large ocean-crossing ships, horses, and effective weapons of many of the explorers, and may have viewed them as divine emissaries, a belief overcome by further contacts that revealed the merely human, although sometimes terrifying, nature of the newcomers. Indeed, the spread of European diseases sometimes caused Native Americans to believe that the bringers of these illnesses, of which they had no previous knowledge or effective means of treatment, were evil wizards or demons. For many, including the advanced civilizations of East Asia and the Islamic world, Europeans were foreign barbarians, particularly for those who had to deal with the violence of many early explorers.

Christopher Columbus after 1493

The famed Genoese explorer Christopher Columbus (1451–1506) is mostly remembered for his discovery of Hispaniola in the Caribbean Sea in 1492, assumed by many to be the initial discovery of the Americas by Europeans. Under the auspices of the Spanish Crown, Columbus continued to voyage to the Caribbean and onto the mainland for nearly another decade. Through his efforts, the multiple islands in the Caribbean Sea were claimed for Spain, as were territories

on the American mainland along the Orinoco River in present-day Venezuela. Oddly enough, he never realized that he never actually reached the New World but instead assumed that he had encountered the Far East up to his dying days. However, his voyages of discovery in the Caribbean resulted in the expansion of Spanish dominion into the Lesser Antilles, the Greater Antilles, and Central and South America.

For his second voyage to the New World, Columbus left Cádiz, Spain, on September 24, 1493, intent on exploring new territories in what he called the Indies, which he had discovered on his first journey of 1492. He embarked on this venture with approximately 1,200 men and 17 ships. By October 13, the ships left the Canary Islands as they had on the first voyage along a more southerly course. Upon arrival in the

Illustration of the voyage of Christopher Columbus that accompanied the 1494 published version of his letter to the world at large. The image was created by the publisher and not based on a true observation. (Library of Congress)

COLUMBUS'S VOYAGES, 1492–1504

Caribbean region, Columbus sighted various islands, naming them as they went along. Among these were the Lesser Antilles of Dominica, Les Saintes, Guadeloupe, Montserrat, Antigua, Redonda, Nevis, Saint Kitts, Saint Martin, Saint Croix, and the Virgin Islands. Columbus and his crews also charted the Greater Antilles of western Hispaniola (Haiti) and Puerto Rico. He left Hispaniola on April 24, 1494, and arrived at Cuba on April 30 and at Jamaica on May 5.

In his third voyage to the Americas, Columbus left with six ships from Sanlúcar in Spain on May 30, 1498. Bartolomé de Las Casas, a notable chronicler of Columbus, went along on this voyage. Columbus led this fleet to the Portuguese island of Porto Santo in the Atlantic Ocean. He then sailed from Porto Santo in Madeira to the

Canary Islands and Cape Verde. He landed on the southern coast of the island of Trinidad on July 31, 1498. In early August, he explored the Gulf of Paria between the present-day states of Trinidad and Venezuela. He explored the mainland of South America, including the Orinoco River; this was the first time Europeans had penetrated mainland America. Columbus also sailed to Chacachacare and the Margarita islands and sighted and named Tobago and Grenada.

Columbus's fourth and last voyage was pursued with the intent of finding the Strait of Malacca in the Indian Ocean. Leaving Cadiz on May 11, 1502, with four ships, he went to Morocco, Martinique, and then on to Hispaniola. Arriving in Santo Domingo on June 29 but denied port, his ships were quartered on the entry to the Rio

➤ ALVISE DA CA' DA MOSTO

Alvise da Ca' da Mosto, (ca. 1432–1488) was a Venetian maritime explorer hired by Portugal and associated with the policies of expansion of Prince Henry the Navigator (1394–1460). Born at the Ca' da Mosto, a palace on the Grand Canal in Venice to which he gave his name, he was acquainted with and reared in the maritime trades of sailing and shipping. He was hired by Prince Henry during a stay in Portuguese territory while on a voyage from Venice to Flanders in 1454. Much like Columbus, Ca' da Mosto was an Italian free agent with no significant ties to his city-state of origin and willing to work for the expansion of Iberian interests. In the service of the Portuguese Crown, Ca' da Mosto explored the Atlantic coast of Africa and discov-

ered several islands off Cape Verde between 1455 and 1456. In his first voyage, he visited the Madeira Islands and the Canary Islands. On the second voyage, in 1456, he became the first European to reach the Cape Verde Islands. He also explored the Gambia River but returned to Portugal after finding hostility in the inland region (present-day Guinea-Bissau) toward interlopers. His discoveries led to increased Portuguese interest and trade in the West African littoral region, later developing into the large-scale Atlantic slave trading system that linked West Africa (with hundreds of thousands of potential African slaves) with the plantation systems of the Americas.

—Abraham O. Mendoza

Jaina. Subsequently, he stopped briefly in Jamaica and sailed on to Central America, arriving at the Bay Islands off the coast of Honduras on July 30, 1502. By August 14, Columbus had landed on the American mainland near Honduras. He spent two months exploring the coasts of the present-day states of Honduras, Nicaragua, and Costa Rica before arriving in Almirante Bay in present-day Panama on October 16. In Panama, Columbus learned from the local people of gold and a strait to another ocean. In January 1503, he and his men established a military garrison at the entry of Rio Belen. By April, the garrison was attacked by indigenous Americans, and the ships were damaged in the midst of the attack. Columbus escaped for Hispaniola on April 16. By May 10 he sighted the Cayman Islands, which he named Las Tortugas after the local sea turtles. In the midst of a storm off the coast of Cuba, his ships suffered more damage. On June 25, 1503, Columbus and his crew stopped in St. Ann's Bay, Jamaica, unable to go farther. For approximately a year, they remained stranded on Jamaica until help arrived in June 1504, allowing them to return to Spain by November.

In these later voyages, Columbus had served as a governor of various colonial enterprises in the Caribbean but was disliked for his harsh measures in regard to both natives and Spanish settlers. Complaints regarding such excesses led to his removal from office and subsequent return

to Spain in 1500. However, given his record of service to the Spanish Crown, he was absolved of wrongdoing and returned to his respective offices. On May 20, 1506, at approximately the age of 55, Columbus died in Valladolid in Spain with the belief that he had found a westerly route to the Far East. Regardless of his geographic oversight, he proved to be a significant figure in this period of world history in the establishment of European hegemony in the Americas.

Spanish Exploration of North America

From the Spanish voyages of exploration beginning with Christopher Columbus in 1492, Spain's interest in the New World eventually expanded to focus on North America and exploring the seemingly endless lands north of the Gulf of Mexico. The West Indies, Central America, and

much of South America belonged to Spain by conquest by the first decades of the sixteenth century and had brought the European nation great wealth, so the vast lands north of those possessions also held great interest and potential. A succession of Spanish expeditions focused on exploring North America and claiming more territory and resources for an expanding empire, but Spain was never able to successfully establish a stronghold there.

The first of the Spanish explorers to come to North America was Juan Ponce de Leon, a traveler on Columbus's second voyage and noted for his conquest of Puerto Rico. Rumors of unexplored lands to the north of Hispaniola reached many Spaniards in the West Indies, and Ponce de Leon sought and received the approval of King Fernando of Spain to take an expedition northward. In April 1513 Ponce de Leon sighted land that he believed to be another vast island and named it Florida (after the Spanish *Pascua Florida*, or Festival of Flowers).

This first expedition explored several coastal areas of the peninsula, and the Spanish made important observations of the diverse plant and marine life before returning to Puerto Rico. A popular and often-repeated legend cites Ponce de Leon's interest in a "Fountain of Youth," restorative waters that many Europeans likely believed existed in the New World; however, this legend was not attached to Ponce de Leon's expedition until after his death. In 1521 Ponce de Leon organized a second expedition to Florida, landing on the southwest coast near the Caloosahatchee River. Ponce de Leon received an arrow wound in a native attack and died shortly thereafter in Cuba.

In 1528 a group of over 300 Spaniards left Florida and set out westward to explore the coastline of the Gulf of Mexico (called the Spanish Sea). This expedition also suffered from repeated native attacks that reduced their numbers significantly and forced them to kill and eat their horses. The remaining 80 survivors were able to take refuge near Galveston Bay in modern-day Texas. Under the leadership of Álvaro Núñez Cabeza de Vaca, this group explored part of Texas, New Mexico, and Arizona for the next eight years. After suffering years of hardship that included some time enslaved by the

THE PUEBLO INDIANS

The Pueblo Indians of New Mexico take their collective name from the first Spanish explorers to arrive in the American Southwest, who noted with interest that these natives lived in villages (*pueblos* in Spanish). While the Pueblos at times found alliances with their Spanish colonizers helpful in their ongoing resistance against their often warlike and aggressive Apache neighbors, they also struggled to maintain their own cultural identity. Spanish missionaries forced the conversion of the Pueblos to Christianity, but many of their ritualistic observances remained. The Pueblo Revolt of 1680 was successful in expelling the Spanish for 12 years, something that no other native culture of the New World was ever able to accomplish. When the Spanish reestablished control of the region in 1692, the Pueblos maintained many of their unique cultural and social distinctions that are preserved even to the present day. The Pueblos remained under Spanish and then Mexican authority until the end of the Mexican War in 1848, when ownership of their ancient lands passed to the U.S. government. The Pueblo economy today still bears the imprint of Spanish influence, thriving on agriculture and the raising of livestock, unknown to them before European contact.

—Cheryl H. White

natives, only 4 men survived from the original group and reached the relative safety of Spanish settlements in Mexico in 1536. Because of the conditions surrounding this expedition, Cabeza de Vaca's accounts of this exploration, published under the title *La Relación*, are uncertain and incomplete.

In 1539 Spanish explorer Hernando de Soto landed near present-day Bradenton, Florida (Espiritu Santo) with an expedition of approximately 600 men. The group traveled north, encountering the hostility of natives, and continued northeast through Georgia and into South Carolina. The evidence is that de Soto passed through North Carolina and turned westward into Tennessee and then southward again. De Soto's men engaged in a skirmish with natives of southern Alabama at a fortification known as Mabila that resulted in the deaths of thousands

of natives and great damage to the Spanish expedition. By 1549 de Soto marched through Mississippi, Arkansas, Oklahoma, Louisiana, and Texas, and his was the first expedition to document the Mississippi River. His death in 1542 scattered the remaining members of his crew, and most settled in Mexico or South America. Although no direct colonization efforts resulted, de Soto's expedition contributed greatly to general knowledge about the geography of North America and led the Spanish to decide against an overt presence there, with the exception of the Florida peninsula and isolated outposts in the American Southwest.

The Spanish did not easily give up on the idea of gold to be found in North America, evidenced by the expedition of Francisco Coronado during 1540–1542. Coronado left Mexico and traveled into the American Southwest in a futile search for gold, which had been found in such abundance throughout Mexico and South America. In the process, Coronado helped open up that region to eventual Spanish settlement and colonization. To the east the Spanish fort at St. Augustine established in 1565 in present-day Florida was the first permanent European settlement in what would become the United States. The settlement served a minimal purpose as a military outpost and did not represent a significant step toward Spanish colonization. A much more substantial effort at colonization of North America began in the Southwest in 1598, when Don Juan de Onate went north from Mexico to claim lands of the Pueblo Indians, previously visited and recorded by Coronado.

Spanish colonists established Santa Fe in 1609 and began demanding monetary tribute and labor from the local natives. The treatment of the natives under the administration of Onate caused troubles for the new colony, leading Spain to remove Onate as governor. Many of the Pueblos converted to Christianity due to the great missionary efforts of the Spanish, and stable and profitable trading relationships also resulted. Because of the threat of neighboring natives (the Apaches), the tiny new Spanish colony exercised great care but steadily grew in size. Interestingly, the Spanish discovered that the great profitable resource of the American Southwest was not the gold or jewels they had

hoped to find but rather the livestock on the expansive ranches of the region.

The missionary efforts of the Spanish, while overall successful in winning converts among the natives, were relentless in attempting to eliminate the old religious rituals that were still culturally pervasive. This led to a Pueblo revolt in 1680 and drove the Spanish temporarily from the colony. The colony was restored by 1696 when the Spanish crushed a final revolt and seized all the lands of the Pueblo. Over time, the Spanish approach evolved to include efforts at assimilation, religious tolerance, and land ownership among the natives. These policies eventually brought about greater cooperation between the Spanish and the natives of the American Southwest, but by the eighteenth century New Mexico was but an isolated colonial outpost with only minor significance to Spain. However, the presence of Spanish influence ensured that future struggles for imperial hegemony among the European powers would involve the lands of North America.

Spanish Exploration of Central and South America

The opening of the European Ages of Exploration and Discovery in the late fifteenth century became possible because of the shift in Europe's political and religious structures, particularly in the Iberian Peninsula. Previously, Europe had been politically fragmented as nobles fought against their kings for power. In the fifteenth century, monarchs began to gain ground in their struggle to centralize power over both the nobles and commoners. In Portugal, the king was the largest landowner in the kingdom, which allowed for more political stability and the freedom to begin

ocean explorations earlier than any other Europeans. Their travels down the western coast of Africa were motivated by the desire for African gold, and eventually by the end of the century their desire became one of finding a sea route to India.

By 1485 a new entrepreneurial explorer appeared on the scene, a man named Christopher Columbus (Cristoforo Colombo as he was known in his native Genoa). Columbus developed a plan to reach India by sea. Instead of rounding the southern tip of Africa as the Portuguese were attempting, Columbus proposed that he could reach India by sailing westward from Portugal into the open ocean. This feat had never been attempted for two reasons: medieval scholars correctly estimated that the distance from Portugal to Asia was roughly 12,000 miles (19,000 kilometers) but incorrectly supposed that there existed no landmass in between. Therefore, any ship that attempted such a massive journey would most likely be left stranded in the middle of the ocean before reaching any sort of land. In addition, the winds also presented a problem. The easterly wind blew toward the west, making it an easy task to sail westward.

Columbus first presented his plan to the Portuguese king, João II, who believed that it was a nearly impossible task to fight against this wind to sail east in order to return to Portugal. The Portuguese king had little faith that the venture could be successfully completed. After being turned down by the Portuguese, over the next few years Columbus unsuccessfully presented his plans to Genoa, Venice, Fernando and Isabel of Spain, and Henry VII of England. None of the initial proposals met with any success, but a second visit with Fernando and Isabel had a more satisfactory outcome. The marriage of Fernando and Isabel in 1469 led to the eventual unification of the Spanish kingdoms in the sixteenth century. In 1492 they gained control of Granada, the last vestige of Muslim territory in the Iberian Peninsula. These two events afforded them the political control and freedom to support exploration. With the help of Italian financiers, the monarchs were able to fund Columbus's first expedition.

On August 3, 1492, Columbus sailed with three ships, the *Santa Maria*, the *Pinta*, and the *Nina*. On October 12, 1492, he sighted land in

➤ THE DEATH OF MOCTEZUMA

The Spanish exploration and conquest of the lands of the New World produced a rich legacy of mystery and legend surrounding encounters with the natives. Of these encounters, perhaps none has inspired the imagination more than the life of Moctezuma II, the Aztec emperor at the time of the arrival of Hernando Cortes. The exploration of Mexico rapidly became a mission of conquest for the Spanish, resulting in a tragic fate for Moctezuma, who died while in Spanish captivity. The details of Moctezuma's capture, imprisonment, and death are unclear, but early Spanish accounts attempted to place the responsibility on Moctezuma himself, claiming that his acquiescence to Spanish domination incurred the ire of his own people. These accounts, including that of Cortes himself, claim that Moctezuma was stoned to death by his own people. Indeed, Cortes quickly accounted for the death of the Aztec emperor in reports to the Crown of Spain. Later native accounts blame Cortes and his men for Moctezuma's demise. While the true events involving Moctezuma remain unclear, it is a certain illustration that the encounters of the Europeans with the indigenous peoples of the New World provoked conflict and an inevitable struggle for control of the land and its resources.

—Cheryl H. White

what is today the Bahamas and named the island San Salvador. Believing that he was in the Indies, Columbus also explored the coast of Hispaniola (today Haiti and the Dominican Republic) and the coast of Cuba. Columbus returned to Spain with several natives, to whom he ascribed the geographic misnomer of "Indian." Columbus did not know that he had discovered a previously unknown world but in fact believed that he had reached some of the barrier islands of Asia. Upon his return to Spain, Columbus stopped in Portugal to inform King João II of his victory. Upon learning that Columbus had landed in India, the king was quick to inform the sailor that a previous bull signed by Pope Sixtus IV in 1481 granted all land south of the Canary Islands to Portugal. Therefore, according to João, India belonged to Portugal, not Spain. This argument resulted in the Treaty of Tordesillas, signed

in 1494, that drew a line of demarcation 370 leagues west of the Cape Verde Islands.

Columbus later organized three more voyages (in 1493, 1498, and 1502), which are often unfairly ignored. Yet they were in many respects greater undertakings. Thus, the second voyage was the largest of Columbus's enterprises and was conceived as a colonizing venture involving some 1,200 men on 17 ships. On that journey, Columbus explored the Caribbean islands, including Puerto Rico and Hispaniola. These islands of the Caribbean were initially a disappointment to Spain, as they seemed to lack the rich and valuable commercial resources of Africa and Asia. The beginning of colonization efforts in these islands led Spain to further exploration, which eventually took them to the continents of the Americas. Future expeditions established a vast new empire for Spain in the New World.

After the initial burst of exploration in the 1490s, Spanish activity lagged for almost a decade. On Hispaniola, Spanish presence was limited to Navidad for 16 years after Columbus's first voyage, although the smaller settlements of Isabela and Santo Domingo were founded in the late 1490s. The turning point in the Spanish colonization of Hispaniola took place in 1502 when some 2,500 colonists reached the island. The island soon became the center of Spanish exploration in the New World. Thus, the northern coasts of the Caribbean were slowly explored, and Juan Ponce de León, who later discovered the Flowery (Florida) Isle, discovered gold in Puerto Rico and brutally suppressed a revolt of the native Taino people. In 1509 Juan de Esquivel led an expedition to Jamaica, but lack of gold or other tradable commodities on the island meant that the Spanish soon lost interest in it. That same year, however, Alonso de Hojeda and Diego de Nicuesa launched two major expeditions to modern-day Colombia, Venezuela, and Panama. While Nicuesa's expedition to Panama proved to be a disaster, Hojeda's expedition proved to be more successful, and despite fierce local resistance and difficult terrain, its survivors established the first European colony in South America, Santa Maria la Antigua del Darién. This colony, together with the founding of the city of Panama in 1519, provided the Spaniards with a new base, outside Hispaniola, for launching exploratory expeditions

throughout South America. Meanwhile, in 1511–1512 the Spaniards, led by Diego Velázquez and Panfilo de Narváez, explored the Greater Antilles and colonized Cuba. Accompanying Velázquez was a minor treasury clerk, Hernán Cortés, who would earn fame for his conquest of Mexico, while Narváez's expedition included a recently ordained priest, Bartolomé de las Casas, who was so stunned by the vicious destruction of the native population of Cuba that he turned into one of the greatest advocates of the rights and protections for the natives.

The Mexican coast was initially reconnoitered by Columbus himself and was scouted by a subsequent expedition in 1508. In 1517 Francisco Hernández de Córdoba led a small expedition to the Yucatan Peninsula, while a follow-up expedition (in 1518) of Juan de Grijalva pushed farther inland on the east coast of Mexico, marking the first recorded contact between Europeans and Aztecs. The news of this encounter caused Spain to organize a third expedition the following year. In 1519 the Spanish conquistador Hernán Cortés landed on the coast of Mexico and began the conquest of the ancient Aztec civilization there. Cortés and a group of approximately 600 armed men on horseback easily intimidated the Aztecs, who had never before seen a European or a horse. Cortés imprisoned the Aztec chief Moctezuma, and many of the Aztec natives died from either conflict or disease. The conquest of that region of Mexico was complete by 1521, and Cortés renamed it New Spain. Cortés continued explorations of the region and launched several expeditions to the west coast of Mexico. He himself crossed the mainland to the southern tip of California in 1535, and the Spanish name for the Gulf of California—the Sea of Cortés—bears testimony to this. Under Cortés' guidance, the Spanish established several ports in western Mexico, which now served as bases for Spanish ships sailing to the Orient. At the same time, Córdoba explored the land of the Chorotegas, Nicaraguas, and Maribios in the mid-1520s, while the task of exploring the northern Caribbean between Mexico and Florida was completed by Alonso Alvarez de Pineda, who traveled the region in 1518–1519.

Meanwhile, in late 1515 Juan Diaz de Solis, who had already gained experience exploring

Yucatan (1506–1507) and Brazil (1508), organized an expedition to find a passage to Asia through South America. He did explore the coastline of present-day Argentina and discovered the mouth of the Rio de la Plata but was killed in a skirmish with the local Charrúa people. His discovery, however, helped another Spanish explorer. Fernando Magellan, or Fernão de Magalhães as he was called in his native Portugal, who began in the employ of Portugal, petitioned the Spanish to finance his expedition to find a passage through or around the Americas to the Indies. Carlos I of Spain, more commonly known as Holy Roman Emperor Charles V, gave his funding and assent to Magellan, who sailed from Seville in August 1519. Magellan first traveled in the wake of Solis and then navigated the horn of South America through the straits that now bear his name, crossed the Pacific Ocean (the first documented crossing of this ocean), and reached the Spice Islands in 1521. This made Magellan the first to circumnavigate the world; however, his discovery had little practical use for the contemporary mariners, since rounding the tip of South America was a truly daunting venture and was largely avoided until the eighteenth century. Thus, much of Spanish exploration of the western shores of the Americas was done from ports that the Spanish established along the coastline. In 1513 Vasco de Balboa made his famous march to the Pacific Ocean from Santa Maria la Antigua del Darién. As he reached the coastline, Balboa waded out into the waters of this “Southern Sea,” as he proclaimed it, and claimed it and its shores for the Spanish Crown. The act was notarized, with the members of Balboa’s party acting as witnesses. The second man, after Balboa himself, to put his name on the document was Francisco Pizarro.

By 1520 Pizarro had already established a reputation as a dedicated and fierce conquistador. He participated in the early expeditions to the Isthmus of Panama, and as he accumulated wealth at the newly founded City of Panama, he pursued new ventures in South America in the 1520s. As a result of these scouting missions, he soon learned of rumors of fabulously rich lands far to the south. After years of trying, in 1528 he finally managed to establish contact, at Tímbez, with the Inca state under the rule of

their chief, Atahualpa. Two years later Pizarro embarked on a larger expedition to the Inca realm, conquering it by 1538. The arrival of the Europeans in the new lands also meant the arrival of European diseases such as smallpox and measles, to which the natives had no previously acquired immunity. As a result, the Spanish conquest of the New World of Mexico and South America was made significantly easier at the expense of the native populations.

Spanish Enter the Philippines

Ferdinand Magellan (1480–1521), a Portuguese mariner, was one of the first Europeans to encounter the Philippine archipelago. After the Portuguese king Manuel I rejected his plan to locate the Spice Islands and establish commercial trading, Magellan took Spanish nationality so that he could undertake exploratory voyages for the Spanish Crown. This had been one of the objectives of the earlier explorer Christopher Columbus, whose journey westward from Europe led to the discovery of the Americas in 1492. Within a few years rivalry between Spain and Portugal for the control of lands and trade routes beyond Europe caused political storms that resulted in several Papal Bulls (decrees). By 1494 the Treaty of Tordesillas established a north-south meridian line 370 leagues west of the Cape Verde Islands and allocated all lands east to the Portuguese and all lands west to the Spanish.

In effect this closed routes to the Pacific Ocean via India to the Spanish, and Magellan set

THE GALLEON TRADE

Manila became a thriving port as well as the seat of government in 1565. Of particular importance was the trade with Spanish America, especially with Acapulco in Mexico. This transpacific trade lasted until 1815 when the Mexican War of Independence began. Galleons brought not only goods but also Philippine natives known as Luzon Men, those exiled for troublemaking and servants, to the west coast of Mexico and North America. This trade began when Andrés de Urdaneta, sailing in a convoy led by Miguel López de Legazpi, discovered a return route from the Philippines to Acapulco. Overall 110 galleons plied the Pacific, with at least three ships sailing each year in each direction. The galleons themselves were among the largest ships of the time and were constructed in the Philippines. Their cargoes were varied but were composed of mainly spices, porcelain, ivory, silk, and lacquerware produced in various islands and parts of mainland Southeast Asia. From Mexico's west coast the goods were taken east overland to the Gulf of Mexico and then to Europe. The Mexican (New Spain) connection was important because it kept the trade in Spanish-controlled land and waters and the goods were paid with silver produced in Mexico.

—A. M. Mannion

out to find a route to the west. On September 20, 1519, with five ships and a crew of 270 men, Magellan set out from Sanlúcar de Barrameda in Andalusia and traveled west. On October 21, 1520, the fleet reached the channel now named the Strait of Magellan and began the passage between the Atlantic and Pacific oceans. By March 16, 1521, Magellan and his remaining crew of 150 became the first Europeans to reach the Philippines when an initial landing was made on the island of Homonhon. On April 7 Magellan sailed to the island of Cebu, where conversions to Christianity took place. Hostility to Christianity of some indigenous people led by Rajah Lapu Lapu resulted in Magellan sailing to Mactan, where he and his army engaged in battle and he was killed. Subsequently, two of the original fleet visited the Maluku Islands (the Spice Islands or the Moluccas, which are part of Indonesia), took on valuable cargo that included cloves, and

set sail for Spain although only one ship, the *Victoria*, under the leadership of Sebastián Elcano, arrived home in September 1522, having circumnavigated the world and brought spices of the East directly to Europe. Four further expeditions were undertaken from Spain between 1525 and 1542, and it was Ruy Lopez de Villalobos, commander of the fourth expedition, who named the islands after Philip II, the Spanish heir who became king in 1556.

It was more than 40 years after Magellan landed that Spanish settlement began in an archipelago comprising more than 7,000 islands located between the South China Sea and the Philippine Sea. The first wave of immigrants was led by the conquistador Miguel López de Legazpi, who arrived from Mexico in 1565 and established settlements in Cebu. Legazpi defeated local resistance from the Muslim leader Rajah Sulayman, and in 1571 Legazpi's company established a base at Manila on the island of Luzon. Manila became the capital, whose initial design is attributed to Jesuit missionaries. The city was the seat of government during the entire period of Spanish rule, first as the viceroyalty of New Spain from 1565 to 1821, when it was administered from Mexico City, and then administered directly from Madrid between 1821 and 1898. For a short time from 1762 to 1764 the Philippines were ruled by Britain. Overall, a number of disparate island communities became united to create a nation. Trade was the major enterprise not only with Spain and greater Europe but also with the Americas; the most important goods were spices, ceramics, and silk. Spanish warfare with indigenous groups, including Muslims of the islands of Mindanao and the Sulu Archipelago, was endemic. Furthermore, the Spanish also fought the Portuguese to maintain Spanish control of the archipelago. The Spanish introduced a number of customs including a social hierarchy and the advocacy of land ownership by individuals and families rather than communal use. Educational and health systems were established, and processes such as printing were introduced often under the auspices of the Catholic Church, which undertook to convert the indigenous population and continues to be a major influence today. Spanish immigrants produced new ethnic groups including the creoles, who were

Spaniards born in the Philippines, and mestizo, who were mixed Spaniards and Malaysians.

Portuguese Exploration of the West African Coastline

The period famously known as the Age of Exploration began with the Portuguese and their voyages west into the Atlantic Ocean and down the western coast of Africa. The person most directly responsible for these voyages is Prince Henry, “the Navigator” (1394–1460). Despite the moniker “Navigator,” Henry in fact never actually participated in the navigations or the education that led to these explorations. Rather, Henry was the financier of these discoveries. As the third son of King João I, Henry would not be given wealth, so he would need to acquire it for himself. He began this quest by obtaining monopolies on things like tuna, soap, and coral.

In the fifteenth century, the Portuguese were in a better position to begin the explorations than any other country in Europe. Unlike countries such as England, France, and the Spanish kingdoms, Portugal had the political stability that afforded it the opportunity to concentrate on other matters. In addition, the desire for African gold and for crusades against the African Muslims drove them to send their ships south. Also, the legend of Prester John and eventually the search for a sea route to India would propel more and more explorers through the dangerous Atlantic.

Until the fifteenth century, European knowledge of Africa was limited to the Sahara as the southernmost area, and this knowledge was only obtained by secondhand knowledge from Jewish merchants who had traded in northern Africa. The capture of the fortress of Ceuta in 1415 was the beginning of Portuguese dreams of becoming an important cornerstone in the global market of gold. While certainly religious

reasons existed behind their motivations to capture Ceuta, it cannot be denied that Ceuta was also strategically important both militarily and economically for the Berbers in northern Africa. With the capture of this city, they hoped to capture an important link in the trans-Saharan trade. Gold had become extremely important to Europe during the late Middle Ages, as more and more countries and cities were using it for their coinage. They soon realized that it would be far easier to access these areas by sea rather than by land. In addition, Prince Henry’s financing brought about the development of the caravel, a boat that was lighter, easier to navigate, and faster than previous vessels used.

In funding these voyages, Prince Henry was mostly looking to enrich his own fortunes, but he became instrumental to advancements in shipbuilding, cartography, and navigational science, as he funded the work of scientists from all over Europe. These progressions led to the discovery of the Madeira Islands (1419) and the Azores Islands (1427). These discoveries encouraged Prince Henry and his entourage of explorers and scientists to continue navigating south along the coast of Africa. Despite the invention of the caravel, exploration was mainly limited to the coast, as the knowledge of the time still did not understand the prevailing winds and how they operated. Straying too far from the coast could spell disaster for a ship and its crew and leave them stranded in the middle of the Atlantic Ocean.

At this time, the southernmost area of Africa known to Europeans was Cape Bojador, on the northern coast of the Sahara. The seas around the cape are extremely rough, plagued by fog, and surrounded by prevailing waves that made it almost impossible to return north, which is why “Bojador” is derived from the Arabic name for the place Abu Khatar, which means “the father of danger.” According to the chronicles, at least 15 voyages had failed to go around the cape before one of Prince Henry’s ships, captained by Gil Eanes, finally made a successful return voyage in 1434. This success broke the psychological barrier that had existed against voyages around the cape and farther south. Two voyages and two years later, voyagers reached Cape Blanco in 1436, and the Sahara had finally been passed. The next voyage did not occur

PORTUGUESE EXPLORATIONS OF THE AFRICAN COAST

until 1441. This voyage was undertaken by Antão Gonçalves and Nuno Tristão to Rio de Oro, where the first Moorish slaves were taken captive. This was the beginning of what would become the African slave trade. While these first slaves taken from Africa mainly went back to Portugal and were used as luxury items by the nobility, shortly after the slaves were sent to the Madeiras to work the sugar plantations that began springing up there.

The beginnings of the slave trade helped finance the explorations down the rest of the coastline. While slaves were at first obtained by

raiding, the Portuguese soon realized that many Africans were more than willing to barter slaves in a peaceful manner. Besides money, the slave trade also provided a psychological boon for the Portuguese, as they were finally provided with a visual benefit to all of the risk being taken. Two years later, Tristão sailed from Cape Blanco to the islands of Arguim Bay. That decade saw the Portuguese vessels going down the coast of Senegal, Guinea, and Gambia. By this time, Henry had obtained sole rights to make war, carry merchandise, or bring back any people or goods from any region south of Bojador without

► SECRECY DURING THE AGE OF DISCOVERY

There has been historical debate over the final years of João II's rule, mainly the years 1487 until his death in 1495. These years showed a halt in exploration, which seems mysterious considering the level of involvement João had shown since he ascended the throne. Jaime Cortesão and his brother Armando posited some very controversial theories in the 1970s in order to explain the reason for this supposed halt in activity. According to them, because João's reign was plagued by the threat of possible rivals, he was forced to conduct many expeditions either in secret or at least with some misinformation involved. Secrecy was very important; if any rivals were to discover the information that the Portuguese had on the route to India, they could have used it to further their own explorations and possibly reach India first. Evidence can be found for several secretive expeditions that were conducted through Ethiopia in João's search for a sea route to India, which supports the idea that he was concerned about the security of the information his men were acquiring. However, the Cortesão brothers, particularly Armando, took the theory a step further by claiming that the lack of documents during this period was proof that João was conducting secret voyages around the Cape of

Good Hope so as not to alert his Castilian rivals to his plans, especially after Columbus's "discovery" of a western route to Asia in 1492. In addition, several other occurrences could possibly lend weight to their theory, including the fact that Vasco da Gama, a minor noble who did not have much experience in seafaring, was given charge of such an important expedition as the one that went to India in 1497. Armando Cortesão claimed that João had already sent a voyage to India in 1495 shortly before his death, but the information was never released because his successor and cousin, Manuel I, wanted to retain the credit of the discovery for himself. Unfortunately for him, there is no evidence that this happened. In addition, the Treaty of Tordesillas, which was signed in 1494, set the line of demarcation as 370 leagues west of the Cape Verde Islands, which goes down the eastern part of modern-day Brazil, six years before the discovery of Brazil by Pedro Alvares Cabral. This theory has been vehemently denounced by other Portuguese historians, who have provided other theories as to why João halted his expeditions. No concrete evidence has been shown to prove either side of the debate; therefore, the mystery remains.

—Monique Vallance

paying the *Quinto*, or the one-fifth tax. This was granted to him by his nephew, Afonso V, and these rights were guaranteed by Pope Nicholas V in 1455 in the bull *Romanus Pontifex*. This quickly stopped any non-Portuguese vessels from encroaching on Africa, as they were now threatened with excommunication. This bull guaranteed that Portugal would retain a monopoly on Africa for the next two centuries. The last discovery made before Henry's death in 1460 was that of the Cape Verde Islands in 1456.

The death of Henry slowed down the explorations for the next 20 years, as Afonso V was more interested in his designs to overtake Castile than he was in following the coast of Africa. Despite this, ships continued to make their way south, reaching the Bisseau Islands and Sierra Leoa, or present-day Sierra Leon and Cameroon (derived from the Portuguese word *camarão*, or shrimp). Perhaps one of the best discoveries was

the discovery of the Gold Coast, in present-day Ghana. This finally brought the Portuguese the source of the African gold that was so coveted in Europe. The Crown finally took control of these expeditions when King João II took the throne in 1481. He ordered a fort built in the Gold Coast area in 1482, moved the headquarters of the Portuguese voyages from Lagos to Lisbon, and invited foreign businessmen to invest, although he made it clear that any pirate activity would be punishable by death. During this same year Diogo Cão began his exploration of the Kongo region and river.

It was soon after Henry's death that the concept of reaching the Indies via the ocean emerged, although in the 1460s this was still a vague idea, as the Portuguese were not sure how that could be achieved. By the 1480s, however, King João was determined to turn this vague idea into a concrete one. After the death of

Diogo Cão, it was now the charge of Bartolomeu Dias to lead the way to India. In 1487 Dias departed from Lisbon and made his way down the coast of Africa, going farther than any explorer before him. He finally made it around the tip of Africa, reaching Kwaaihoek, on the eastern coast of South Africa, in March 1488. He originally intended to travel all the way to India, but his crew mutinied and refused to go any farther. Therefore, Dias discovered what he dubbed the “Cape of Storms” on his return voyage to Portugal. João II would name this cape the Cape of Good Hope, as it represented the possibility of finally reaching India by sea. While the Cape of Good Hope is not the southernmost tip of Africa, it is the point where ships began sailing more east than south.

All of the explorations down the western coastline of Africa would finally culminate in the voyage of Vasco da Gama in July 1497. Dias joined da Gama on this voyage by captaining one of the ships until reaching the Cape Verde Islands. Da Gama’s voyage reached India in 1498, thus achieving the dream set forth by João II, although this occurred after his death. It was the discovery of this route that catapulted Portugal to being among the richest countries in Europe and labeled João’s successor, Manuel I, as “the Fortunate.”

Portuguese Exploration of Amazonia

The late fifteenth century saw an increase in maritime activity leaving Europe and exploring what had previously been a mystery to the

Europeans. The Portuguese had led the way in these expeditions as they voyaged their way down the western coast of Africa in search of a sea route to Asia and its wealth of spices. When Vasco da Gama reached India in 1498, he returned to Portugal triumphant with a shipment of cinnamon and pepper, proof that the Iberian kingdom was on the verge of becoming wealthy beyond belief. It was the return of Vasco da Gama that prompted King Manuel I to immediately send out another ship bound for India. This time Pedro Alvares Cabral captained the ship. Cabral spoke to da Gama and received instructions on how to use the prevailing winds to swing around the southernmost tip of Africa.

Cabral’s expedition consisted of 13 ships and 1,500 men, including Bartolomeu Dias, the first man to sail around the Cape of Good Hope. They left on March 9, 1500, and the ships sailed away from Portugal pointed in a southwestern direction. However, those prevailing winds proved to be tricky, blowing the ships away from Africa rather than toward it. Finally land was sighted on April 22, a land that would later be dubbed “Brasil.” However, Cabral’s main purpose was not to discover new territory but instead to sail to India, so he could not stay long in this new land. The ten days during which he stayed in Brazil were spent attempting to chart its location, exploring the topography, and attempting to communicate with the people. The next day one ship was sent to Portugal to alert the king of the news, along with a sample of a tree that would later be called brazilwood, a tree that became high in demand for its dye. Some convicts, or *degradados*, were left behind with instructions to learn about the area and the people and their language. The Treaty of Tordesillas provided that the line of demarcation would fall 370 leagues (1,280 miles or 2,056 kilometers) west of the Cape Verde Islands, which falls just west of present-day São Paulo.

The ship headed for Portugal reached its destination in 1501, and King Manuel immediately sent a small expedition to explore Brazil. At least one of the convicts was able to serve as an interpreter and intermediary between the Portuguese and the natives. Exploring the land would prove to be a dangerous venture, as some of the indigenous people were cannibals. By 1511 news

was circulating throughout Europe about Brazil, glorified as a tropical paradise. Many believed Brazil to be a large island, and if it was, then Asia could still be reached from the other side. The goal of another expedition in 1511 was to see if there was a way to reach Asia from Brazil, but instead they found the La Plata estuary. The Portuguese continued to build settlements along the coast of Brazil but did not stray too far into the interior because of the dangerous natives and jungles. Two Spanish explorers managed to navigate some distance down the Amazon River, but the Portuguese would not attempt the same venture for a century.

The search for a shorter route to Asia was always on the mind of the Portuguese king, and Columbus's discovery of a "new world" made that dream seem much closer. Another possible direction that had not been given much attention by 1500 was a northwestern one. As of yet it was not possible to know the extent of the North American continent, and it was hoped that if an expedition could sail far enough, it could go over the Americas and reach Asia faster than around the Horn of Africa. It was with this aim that an expedition of two caravels departed from Lisbon in 1500 under the leadership of João Vaz Corte-Real (ca. 1450–1501). Very little is known about the actual voyage taken, but it is probable that Corte-Real sailed as far north as Greenland, as an Italian map commissioned in 1502 shows the southern tip of Greenland as "A ponta d'Asia." It is unknown what else he saw during this voyage, but we do know that he was unable to land and was forced to return to Lisbon. The following year Corte-Real set sail again, this time with three caravels, on May 15, 1501. He once again sailed toward Greenland and went farther north than he had the first time. However, he encountered icebergs and pack ice, making it impossible to land. He then crossed the Davis Strait and encountered a coast that he described as having pine trees and many rivers. Modern historians surmise that this area is present-day Newfoundland, as the Italian map mentioned above does not show any land farther north than the east coast of Newfoundland. Unfortunately the expedition encountered a storm, and Corte-Real's ship was lost at sea.

When João did not return, his brother Miguel set sail to locate him. If one considers Greenland

➤ MANUEL I

Manuel I of Portugal (1469–1521) oversaw the age of Portuguese exploration and expansion at its apex. In 1495 he inherited the throne from João II, who was both his cousin and his brother-in-law. When Manuel assumed the throne, explorations of the African coast were already under way. Under his patronage, Portuguese explorers reached Greenland in 1495, India in 1498, and Brazil in 1500. In addition, the Portuguese were exploring the African coastline as well as the Indian Ocean. These expeditions as well as Portuguese entrance into the slave trade did much to increase the wealth and fame of Portugal, and Manuel was acclaimed the richest monarch in Europe. After 1500, following numerous naval victories, Portuguese monopoly of the spice trade was firmly established.

—Monique Vallance

an arctic region, then this can be considered the first polar relief expedition. After an exploration of Newfoundland and Labrador, the ships agreed to separate in order to cover a wider search area. The agreement was to reconnoiter on August 20, but Miguel's ship was never seen again. When this second brother failed to return, the remaining Corte-Real brother, Vasco Anes, planned a second relief expedition; however, King Manuel refused to give him permission to leave, fearing that he too would be lost. This ended any other Crown-sponsored expeditions of North America by the Portuguese.

Throughout the sixteenth century, Brazil's main exports were brazilwood and sugar. Other than that, there did not seem to be any other wealth that could be attained; therefore, they concentrated more on their Asian empire. The combination of the Dutch Rebellion against the Spanish and the union of the Spanish and Portuguese Crowns at the end of the sixteenth century made the one-time allies instant enemies. Increased Dutch pirate activity caused the Portuguese to begin losing their Asian possessions until 1609, when the Spanish king Philip III signed a 12-year treaty with the Dutch that allowed them to trade in Brazil. Once the treaty expired in 1621, the Dutch began to concentrate

more on exploring Brazil, which led to the next expedition to South America. Although the Treaty of Tordesillas had given Brazil to Portugal, the Amazon River was firmly on the Spanish side. However, the Spanish were more concerned with the wealth of Peru to be too bothered with the Amazon. The French began appearing at the northern part of the Amazon, which prompted the Portuguese to build Fort Presépio in what is today's Belém in order to defend the region. This fort became the starting point for another expedition in 1621. Against the danger faced by the French and the Dutch, the Spanish king, who for the time being was also the Portuguese king, decided to allow the Portuguese to explore the lower part of the Amazon. This expedition set sail on June 21, 1621, and was led by Luis Aranha de Vasconcelos. He sailed 400 leagues (1,400 miles or 2,200 kilometers) up river and was the first to map it. His voyage laid the foundation for Portuguese authority in the lower Amazon region.

The person responsible for establishing Portuguese authority throughout the entire Amazon region was Captain Pedro Teixeira. He attacked several English and Dutch units along the Amazon. In addition, he captained another expedition in 1637. This expedition was the biggest ever, with 80 Portuguese and over 1,200 aborigines and Africans. One year later the group reached Quito, in present-day Ecuador, without much incidence. This journey encompassed almost the entirety of the Amazon and was the first of its kind. Upon their arrival in Quito, the Spanish viceroy in Peru became concerned at the Portuguese activity on the Amazon and insisted that they allow two Spaniards to accompany them on their return journey so that the river could be thoroughly mapped and documented.

As the century wore on, the Portuguese continued their push through the upper Amazon despite the fact that the Treaty of Tordesillas directed that the area was Spanish. However, the Spanish empire was stretched too thin and could not afford the time, men, or money to fend off the Portuguese. By the end of the seventeenth century gold was discovered in Brazil, and the ensuing rush of immigration from Portugal permanently decided that the entirety of

the Amazon region would be in the hands of the Portuguese.

Portuguese Expansion in the Indian Ocean

The Indian Ocean was a historic center for trade and empires in world history throughout much of human history. Portuguese expansion into the Indian Ocean began with Vasco da Gama's voyage to Goa (in western India) in 1498. At this time, Muslim rulers and traders had dominated the Indian Ocean for several centuries, as it connected several major empires in Asia and the Middle East. As a result, the Indian Ocean trade brought enormous wealth and opportunities, opportunities that Europeans sought in their quest to locate new trade routes to Asia.

Da Gama succeeded in locating a sea route to India by traveling around Africa and the Cape of Good Hope. However, da Gama's trip to India was one of frustration, as he found Muslim merchants dominating the trade in every port in east Africa and India. Furthermore, da Gama's aspiration to convert Indians was unsuccessful. In addition, he found few buyers for the goods he sought to trade and thus returned to Portugal only after purchasing spices and luxury goods with silver rather than profits from trade. Indeed, in Calicut his offerings of European-made goods offended the local ruler. Da Gama further exacerbated the situation by kidnapping some residents to display to the court in Lisbon.

In 1502 da Gama returned to the Indian Ocean with 20 ships. Using force and intimidation, he was able to quickly secure the shoreline of much of east Africa due to lack of unity

among the various small city-states that dotted the coast. He carried out acts of piracy against any Muslim ship he found in the waters, killing all aboard and plundering the ships before leaving their burning hulls behind. Villagers and fishermen were not spared from da Gama's terror as he attacked them indiscriminately, bombarding them from the safety of his ships. Da Gama justified his actions in the name of Christ, as he was filled with a crusading zeal following the Iberian Reconquista.

Part of the Portuguese expansion into the Indian Ocean revolved around the quest for the legendary Prester John, whom they ultimately concluded was the Negus of Ethiopia. However, before they came to this realization, it was thought that with the power and wealth of Prester John, the forces of Christianity would destroy dominance in the region by undermining the wealth of the Muslim trade. Ultimately the Portuguese did not need Prester John's assistance for this, as they attacked any non-Portuguese ship. Nonetheless, the Portuguese-Ethiopian alliance proved useful in preventing Ottoman influence from solidifying in east Africa. The alliance prevented the Ottomans from penetrating the interior of east Africa in 1543. The Ottomans remained the dominant force in the Red Sea and the Gulf of Aden, but the Portuguese attempted to establish bases around the perimeter of the Indian Ocean to monopolize trade and control choke points like the straits of Malacca and Hormuz. Indeed, their superior firepower allowed them to succeed at all points except the Ottoman-controlled Aden.

It is astonishing that Portugal, whose population was less than most of the Indian Ocean kingdoms they terrorized, succeeded at all. A key reason for their success was their ships and cannons, but another reason was the nature of the kingdoms. Although the Ottomans succeeded in preventing Portuguese dominance in the Red Sea, they were too busy on other fronts to make a concerted effort elsewhere against the Portuguese. Meanwhile, the Safavids and the Mughals were less concerned about the naval power of the Portuguese. Most of the ships that the Portuguese attacked were merchant ships rather than warships. Yet for all of their naval

➤ PORTUGUESE SHIPS AND THE INDIAN OCEAN

In addition to using terror and piracy to help establish power, the Portuguese also relied on ships and guns in order to assert influence in the Indian Ocean.

Most of the Muslim naval vessels in the region were galleys, whose primary method of attack was ramming. They also carried a few cannons but at the fore and aft and thus were not able to provide broadside attacks. Furthermore, the cannons could damage ships but were not extremely powerful due to the limited amount of deck space, as the recoil of a heavy cannon could send it off the deck and onto the rowers.

The Portuguese, however, brought their caravels with two to four masts, including lateen sails, and loaded them with cannons. Although the caravel rarely exceeded 164 feet (50 meters), it was wider than the galleys used along the coasts of the Indian Ocean, thus allowing more space for the recoil of the cannon. Furthermore, with no oarsmen, the Portuguese could place cannons on the deck and also below deck. Beginning in the 1500s, gun ports below deck increased the amount of cannons in use, and heavier cannons usually were used below deck. Their shots could open huge holes into the hull of the enemy galleys and from a safe distance, unlike a ram on a galley.

—*Timothy May*

dominance, the Portuguese could only hold the coastline, as any army in India was larger and well organized. Only by acting in concert with other rulers did the Portuguese find success in the interior. As long as they did not cause trouble inland, most rulers did not trouble themselves with ridding themselves of the Portuguese and viewed them as simply replacing one set of merchants with another. Indeed, when Muslim minorities in Hindu-majority kingdoms in southern India armed and organized themselves against the Portuguese, the Hindu princes often allied themselves with the Portuguese out of fear of a Muslim rebellion.

Despite the dominance and rapacious activities involved in the Portuguese expansion, they did suffer setbacks. By 1580 the indiscriminate Portuguese attacks on local shipping

in east Africa finally resulted in coordinated attacks on their own ships and bases. Ultimately the Portuguese also experienced a retreat from the Indian Ocean. The threat they faced, however, came not from the victims of their expansion but rather from English and Dutch trading companies, which were initially welcomed by the Muslims. Indeed, the only Muslim power to successfully resist and counter the Portuguese expansion was the nascent seaborne empire of Oman, which stripped away Portugal's east African possessions north of Madagascar. By the mid-eighteenth century, only a few Portuguese possessions remained in the Indian Ocean.

Vasco da Gama, Renaissance Crusader

Vasco da Gama (ca. 1469–1524), Portuguese explorer, first count of Vidigueira, and discoverer of the sea route to India, was born in the coastal town of Sines about 1469. His family had long-standing service ties to the Crown in its struggles against Castile and Islam, and Vasco's father, Estevão, had won grants, including the post of *alcaide-mor* (governor-major) of Sines, for these services. He also became a *commandery* holder, or possessor of a revenue-generating land grant, in the powerful crusading Order of Santiago, thus elevating the family's status, a process that would culminate with his son's career.

Not much is known about the early years of Vasco da Gama's life. He received a solid education in nautical matters and also demonstrated

martial skills in campaigns against Castile. In 1492 King João II (r. 1481–1495) selected da Gama to confiscate French shipping in the ports of the Algarve in retaliation for the French seizure of a Portuguese ship returning from Africa loaded with gold. He accomplished this task with great brevity.

In 1497 King Manuel (r. 1495–1521) selected da Gama to command the epic expedition to India that successfully ended the search for a sea route to Asian spices begun during the days of Prince Henry (1394–1460). The four-ship fleet (*São Gabriel*, *São Rafael*, *Berrio*, and a store ship) departed Lisbon on July 8, 1497, with 170 men aboard. After stopping at São Tiago (July 27–August 3) in the Cape Verde Islands, da Gama and his fleet headed out into the Atlantic to exploit the prevailing winds. On November 8 the fleet reached Santa Helena Bay and on

Portuguese navigator Vasco da Gama was the first to sail from Portugal to India, opening up new routes for the spice trade. Illustration from Pedro Barretto de Resende's historical and topographical account of the Portuguese settlements in the East Indies, 1646. (The British Library/StockphotoPro)

➤ CALICUT

The following appears in the *Logbook (Roteiro) of the First Voyage of Vasco da Gama*. The journal was kept by an anonymous crew member aboard Vasco da Gama's ship, the *San Rafael*. This account of the long and costly journey of spices from Calicut to the Mediterranean clearly indicates why the Portuguese desired direct access to the markets of the Indies.

"From this country of Calicut . . . come the spices that are consumed in the East and the West, in Portugal, as in all other countries of the world, as also [are] precious stones of every description. The following spices are to be found in this city of Calicut, being its own produce: much ginger and pepper and cinnamon. . . . Cloves are brought to this city from an island called Melqua [Malacca]. The Mecca vessels carry these spices from there to a city in Mecca [in Arabia] called Judea [Jeddah], and from the said island to Judea is a voyage of 50 days sailing before the wind. . . . At Judea they discharge their cargoes, paying customs duties to the [Mamluk] Grand Sultan. The merchandise is then transshipped to smaller vessels,

which carry it through the Red Sea to a place close to Santa Catarina [Monastery] of Mount Sinai, called Tuuz [El Tur] where customs dues are paid once more. From that place the merchants carry the spices on the backs of camels . . . to Quayro [Cairo], a journey occupying ten days. At Quayro duties are paid again. On this road to Cairo they are frequently robbed by thieves. . . .

At Cairo the spices are embarked on the river Nile . . . and descending that river for two days they reach a place called Roxette [Rosetta], where duties have to be paid once more. There they are placed on camels, and are conveyed in one day to a city called Alexandria, which is a sea-port. This city is visited by the galleys of Venice and Genoa, in search of these spices, which yield the Grand Sultan [an annual] revenue of 600,000 cruzados."

Roteiro, E. G. Ravenstein, ed. and trans., *A Journal of the First Voyage of Vasco da Gama, 1497–1499* (Hakluyt Society, 1898), First Series, No. 99 (reproduced by Burt Franklin [1963?], pp. 77–8. Modernized by A. J. Andrea.

November 22 rounded the Cape of Good Hope. Once in the Indian Ocean, da Gama confronted the entrenched economic power of Muslim Arab merchants. This religious and economic hostility complicated his task along the East African coast during a stay at Mozambique Island (March 1498) and especially at Mombasa (April 1498), where the local sultan sought to storm the fleet in a midnight raid. Da Gama received a more favorable reception at Malindi, where he hired a skilled pilot to guide the Portuguese fleet across the Arabian Sea to the pepper-rich Malabar coast of India by May 1498. His mission of arranging both a treaty and the purchase of pepper in the key port city of Calicut was complicated by the intrigues of Arab merchants with the local Hindu ruler, the Zamorin (*Samudri raja*), and da Gama's rather paltry gifts. Nevertheless, his resolve overcame these problems, and da Gama departed in August with a respectable cargo of spices. Although the return trip to Portugal was

complicated by fickle winds, the *Berrio* and *São Gabriel* reached Lisbon in July and August 1499, respectively. After burying his brother Paulo on Terceira in the Azores, da Gama reached home in September. He received the right to use the prestigious title "Dom," a hefty annual pension, and other rewards, including the title "Admiral of the Indian Seas."

In 1502, to avenge the massacre of Portuguese factors, or merchants, left at Calicut by the fleet of Pedro Álvares Cabral (1500–1501), King Manuel dispatched 20 well-armed ships under da Gama. He used this formidable force to intimidate the sultan of Kilwa on the East African coast into fealty (July 1502), to intercept Muslim shipping arriving on the Indian coast, and to inflict a decisive defeat on an Arab fleet in the service of the Zamorin (February 1503). His ruthless nature was revealed on this voyage when he burned several hundred Muslim pilgrims alive aboard a captured ship in September 1502. Da Gama

returned to Lisbon in October 1503 and received additional rewards. During the following two decades he labored in Portugal to consolidate his social and economic position. His marriage to Dona Catarina de Ataíde produced seven children. Despite problems with the mercurial King Manuel, da Gama at last entered the ranks of the senhorial elite in 1519 when he was created the first count of Vidigueira.

By 1524, although the Portuguese empire in Asia stretched from Mozambique to Indonesia, corruption had begun to infiltrate this impressive imperial edifice. The young king John III (r. 1521–1557) appointed da Gama viceroy in that year to address these problems. Sailing with 14 ships in April 1524, da Gama reached India in September and undertook an impressive reform campaign that was tragically cut short by his death at Calicut on Christmas Eve 1524.

Da Gama's life and career mirrored the rise of Portugal. Nautical expertise, military prowess, ruthlessness, and religious conviction entrenched his personal and familial fortune while Portugal, at the same time, achieved its Golden Age.

The First Englishmen in India

Unlike their Portuguese or Dutch rivals who had been trading with India since the early sixteenth century or 1595, respectively, early English attempts to reach the subcontinent ended badly. The merchant-soldier James Lancaster (1554/1555–1618) and the crew from his 1591–1594 voyage returned to England aboard French ships. Commercial interests generally drove Elizabethan-Jacobean policy, but Lancaster,

the first Englishman to sail into the Indian Ocean, was, like Francis Drake (1540–1596) and the other Elizabethan Sea Dogs, far more interested in capturing prizes than in trade. The failure of repeated expeditions in the last quarter of the sixteenth century is reflective of both deficiencies in English maritime practices and a lack of interest in long-distance trading with the East Indies. Raiding Spanish possessions in the Atlantic basin offered privateers far richer prospects. However, Dutch success inspired 101 London merchants in September 1599 to pledge £30,000 for another voyage. The prospect of peace with Spain nixed their plans almost immediately, but planning resumed in September 1600 following the collapse of peace talks. A royal charter creating the East India Company (EIC), with a 15-year monopoly on trade east of the Cape of Good Hope, was issued on New Year's Eve that same year. The company's first fleet of five ships was dispatched in early 1601 under the command of Lancaster, who was also a director of the EIC, and returned to England roughly 22 months later. Although profits were less than expected, the expedition did establish an English presence—albeit tenuous—in the coastal trading posts of the Indian Ocean.

Hundreds more largely anonymous English mariners, soldiers, and company officials would follow in the decades ahead as the EIC sought to expand its trade. It is possible that Englishmen could have arrived any time in the sixteenth century through service with the Portuguese. There is some evidence to suggest that two men, Lançarote Barbudo and Estevam Lopez, wounded in the siege of Diu in 1546, were English. However, the first Englishman known conclusively to have to set foot on Indian soil was Thomas Stephens (1549–1619). The son of a merchant, Stephens was born in Wiltshire and studied at Winchester College and later Oxford. In 1575 he traveled to Rome to enter a Jesuit order and four years later would sail on a Portuguese ship for Goa via the Cape of Good Hope. Outside of one year spent at the Vasai Fort, north of Bombay (Mumbai), Stephens spent the remainder of his life proselytizing in Goa, eventually mastering the local language, Konkani, as well as Sanskrit and the more literary Marathi. First published in 1616, his most lasting accomplishment is the *Purana Christã* q an epic tale written in the local vernacular that

► SIR THOMAS ROE

The only son of a prosperous landowning clothier from a village in Essex, Thomas Roe (1581–1644) was educated at Magdalen College, Oxford, and enrolled in the Middle Temple, one of the four Inns of Court, in 1597. Ostensibly designed to train barristers, the Inns of Court were the intellectual heart of London and generally the reserve of gentlemen. A quick wit, private income, and family connections enabled Roe to overcome his common birth and obtain a position in the late Elizabethan court. Knighted early in the reign of James I (r. 1603–1625), Roe accompanied the delegation dispatched to Spain to witness the ratification of the 1604 Treaty of London. It was an auspicious beginning, but to achieve high office Roe needed to demonstrate his competency in matters of exploration, politics, and soldiering.

In 1607 Roe began promoting the colonization of Virginia and commanded the 1610–1611 expedition to Guiana—the 1,000 miles (1,600 kilometers) of largely unexplored coastline between the Orinoco and Amazon rivers—in the futile search for the treasures of El Dorado. Conflicts between

James I and the House of Commons led to the dissolution of Parliament only a few months after Roe's election in 1614. Roe returned to soldiering in the Low Countries, but in November 1614 James I named Roe ambassador to the Mughal empire. Returning in September 1619, Roe resumed promoting tobacco cultivation in Virginia and on the Amazon, but the outbreak of the Thirty Years' War ended his political career. His anti-Catholic Spanish sentiments saw him banished to Constantinople as English ambassador (1621–1629). Roe spent the next two years traveling the Baltic and trying to forge an anti-Habsburg coalition. Appointed to the Privy Council in 1640, Roe spent the last years of his life futilely trying to mediate the growing rift between Charles I (r. 1625–1649) and Parliament and also worked on occasional diplomatic efforts to end the Thirty Years' War. Public acknowledgment of Roe's accomplishments would not come until the twentieth century, by which point even the location of his tomb had receded into the mists of history.

—Sean Kelly

combined aspects of the Hindu religion with the narrative of the Old and New Testaments. Its popularity among Indian Christians continued into the early years of the twentieth century. Stephens's letters to his father about life in Goa encouraged English merchants to consider the trade possibilities of India. Although a Jesuit missionary, Stephens never forgot that he was also an Englishman. When four English merchants, accused of infringing upon Portugal's trade interests in the Persian Gulf, arrived in Goa for interrogation in December 1583, it was Stephens who helped secure their release, having previously been introduced to one of them by an acquaintance from his days at Oxford.

In the early decades of the seventeenth century, the EIC played an insignificant role in Indian commerce. Real power lay in Delhi, permanent seat of the Mughal emperor. Trade occurred at the discretion of the emperor, Jahangir (r. 1605–1627). The EIC also needed the cooperation of local officials. Henry Middleton (d. 1613), who commanded the EIC's sixth voyage, for example,

frustrated at the reception he received at Surat in the fall of 1611, seized Indian ships in the Red Sea in retaliation and conducted trade on his own terms. Months later Thomas Best (1570–1639) established a factory or trading station at Surat. Thanks to the ineptitude of the Portuguese, who seized a ship belonging to the emperor's mother in 1613 and two years later sent a fleet to attack Surat and the English, Jahangir henceforth was less willing to heed Portuguese demands to expel the English. The broadside of an East India-man was at worst equal to the Portuguese ships, and Jahangir feared both. At the urging of the EIC, James I (r. 1603–1625) dispatched the first English ambassador to the Mughal empire, Sir Thomas Roe, who arrived less than a year after the defeat of the Portuguese attack on Surat. It took several months for Roe to reach the city of Ajmer, but in January 1616 he formally presented his credentials to Jahangir. The language of the Mughal court was Persian, so Roe relied on interpreters throughout his ambassadorship. He spent over three years trying to persuade—or more

accurately bribe—Jahangir and his senior courtiers to sign a formal treaty that guaranteed the trading rights of the EIC throughout the Mughal empire. Roe never succeeded. However, thanks to the favorable impression that he and his gifts made on Jahangir, Roe did win the right for the EIC to trade freely and govern its officials according to English political and religious customs. He also suggested changes to trade practices of the EIC, including initiating trade between Surat and the Red Sea port of Mokha (present-day Al Mukna). Company directors in London were pleased with Roe, awarding him a £1,500 bonus. Nevertheless, the mural in St. Stephen's Hall, Westminster, depicting Roe's embassy as one of the eight seminal events in English history between the time of Alfred the Great (d. 899) and the 1707 Act of Union with Scotland would never have occurred had the EIC not gone on to replace the Mughals as the paramount power in India in the ensuing two centuries.

- the northeastern coast as the leader of an expedition financed by King Henry VII, the first European expedition to the North American continent since Leif Ericson's voyage in the eleventh century. Henry VII of England (r. 1485–1509) issued letters patent to Italian explorer John Cabot in 1496 expressly authorizing him to explore the region of North America, at least partly motivated by the growing power of Spain but also in the hope of discovering the Northwest Passage. Cabot's idea was that by traveling westward from Europe on a more northerly track at higher latitudes, the distance to Asia would be shorter. After an aborted first attempt at sailing from Bristol in 1496, Cabot successfully reached the "land of America" in June 1497. The precise location where Cabot's expedition made landfall is the subject of considerable controversy among historians, but Newfoundland is the most likely site. During this voyage Cabot made landfall long enough to claim the land for England but made no extensive efforts at inland exploration. Although Cabot's expedition failed to find the Northwest Passage he was searching for, it served to launch a series of further explorations and led to English claims to have dominion over the territories they visited. Those land claims notwithstanding, nearly a century more passed before England pressed any serious efforts at further exploration or colonization. The prevailing foreign and domestic concerns of England in the sixteenth century postponed further efforts to exert any English influence in the New World.

Much of the interest that the English had in the New World was its novelty as well as its commercial potential. The idea of new untouched lands offered a vision of hope for those disillusioned by the Old World of Europe, and this notion found expression in the literature of the sixteenth century. Thomas More's *Utopia*, published in England in 1516, described a perfectly ordered civilization that developed on a remote island discovered in the New World by associates of Amerigo Vespucci. In many ways, More's *Utopia* was a revealing portrait of the disillusionment that many had with the social ills of the age. Also, rapid economic changes in England led to an English dominance in the production of raw wool. This was a development that meant the enclosure of common lands, once worked

English Exploration of North America

The first recorded contact of the English with North America dates to 1497, when John Cabot (Giovanni Caboto), an Italian explorer, came to

communally by feudal populations and now needed for grazing sheep. A state of social upheaval resulted.

One significant effect of the enclosure movement was a decline in agricultural production and high rates of unemployment. A rising merchant class emerged as a result of the increased wool production, however, and this trade rapidly expanded to include not only raw wool but also finished cloth products. Merchants formed companies for the expansion of foreign trade, and this development pushed the need for more and more markets for English goods. Once again, the New World seemed an intriguing possibility.

In addition to the obvious economic and commercial motives behind English exploration of North America as having potential for expanding the nation's global market reach, there was also a religious incentive brewing. The European and English Reformations created a general state of religious upheaval by the mid-sixteenth century. The decision of Henry VIII to break with Rome in 1534 created a truly nationalized church in the Church of England. Following his death, England experienced varying degrees of religious turmoil during the reigns of Edward VI (r. 1547–1553) and Mary I (r. 1553–1558). The overtly Protestant influence of Edward's government followed by the sudden restoration of Roman Catholicism under the reign of Mary created tensions and forced exiles to the continent of Europe for religious convictions. The reign of Elizabeth I (r. 1558–1603) sought a comprehensive religious settlement that eventually restored religious stability in England for all but the most extreme faction of Protestants, known as the Puritans. Among these religious discontents would come some of the first to settle in the English claims of the New World.

The first attempt at English colonization in North America failed. The pioneers of English exploration during the reign of Elizabeth I were Humphrey Gilbert and Sir Walter Raleigh. The queen granted these men exclusive rights to explore and possess the lands of the New World, and the first expedition to result from this royal commission was to Newfoundland in 1583. The following year, Raleigh took a small expedition to North America and returned to London with two natives. Queen Elizabeth gave Raleigh

➤ HENRY VII AND OVERSEAS EXPANSION

At the time of the first English contact with the new lands of North America, Henry VII occupied the throne. Because England had only recently emerged from a series of dynastic civil wars known as the Wars of the Roses and because Henry VII's own Lancastrian claim to the Crown was tenuous, he perhaps saw New World exploration as a means of advancing his prestige among other European nations. A successful policy of expansion in the New World would have meant increased wealth for England. However, the overseas exploration policy of Henry VII appears to have been less primary to him than the role of securing domestic control and building a healthy treasury. Henry's fiscal policies, known to represent his personal frugality, explain his limited endorsement and interest in large seagoing voyages of exploration. His government rejected the proposal of Christopher Columbus as the Italian sought financing for his first voyage before approaching Spain. The interest generated from the voyages of Columbus likely contributed to Henry VII's agreement to sponsor John Cabot's venture in 1497, representing the only such major effort of his reign.

—Cheryl H. White

permission to name the region he explored Virginia, in honor of his Virgin Queen. The English government did not finance the expedition, however, so Raleigh was left to find his own investors for the colonial effort at Roanoke Island. However, two separate efforts to settle Roanoke Island failed, and what became of the English settlers there still remains a mystery. This served to lessen English enthusiasm for colonization efforts, and the Elizabethan government undertook no more such expeditions. However, when Philip II launched his Spanish Armada against England in 1588, the decisive English victory in that sea battle effectively supplanted Spain's maritime dominance with that of England.

In 1606 King James I issued a charter to divide colonization efforts in North America between two companies. The London Company received the rights to colonize the southern regions, while the Plymouth Company received the rights to the northern regions for settlement. Because of these

EARLY EUROPEAN PENETRATION OF NORTH AMERICA

two companies, the first lasting English settlements in North America developed. However, money and financing remained an obstacle, and the London Company was able to evolve much more quickly than the Plymouth Company because of the readiness of investors. Only a few months after being chartered, the London Company was sufficiently organized to launch a party of 144 men bound for Virginia aboard the *Susan Constant*, the *Discovery*, and the *Godspeed*. In 1607 the English established its first permanent settlement in Virginia at Jamestown.

In 1620 the first wave of religious immigration to the New World of North America began. The king granted permission for the Virginia Company to take a group of Pilgrim separatists from Plymouth, England, to what would become Massachusetts. The decision of the king to allow the migration of these religious dissidents is

important in that it began a period known as the Great Migration, which lasted until 1649. The original destination of this group was likely the area of the Hudson River near what is present-day New York, but approaching winter and harsh coastal weather conditions led them to an area just north of Cape Cod. The English who settled these early colonies essentially transplanted the society of the Old World into the New World, yet at the same time the isolation and distance from England gradually contributed to the emergence of new American identities and societies.

French Exploration of North America

The French exploration of North America came decades after the first Spanish and English journeys to the New World. The reasons for the French delay in turning its attention to the newly discovered lands lay with a struggle for the balance of power in Europe. The Habsburg-Valois rivalry and the Italian Wars of the late fifteenth and early sixteenth centuries concentrated the French focus on European affairs, and it was not until the reign of Francis I that France turned its attention across the Atlantic Ocean. Like England, the initial efforts of France likely centered on finding the rumored “Northwest Passage” to the lucrative trading markets of the Orient. However, French intentions quickly turned from exploration to colonization. As a result of the French exploration of North America, they established forts, outposts, and trading settlements that would become cities. These include such places as Quebec, Detroit, St. Louis, Mobile, Biloxi and New Orleans.

In 1524 King Francis I sent an Italian seaman named Giovanni Verrazano to explore the Atlantic coast of North America. Verrazano explored the Chesapeake Bay region. His expedition reached North Carolina, and Verrazano wrote to Francis I that he believed that the Pamlico Sound was the beginning of the Pacific Ocean. This belief led to the inaccurate mapping of North America for centuries. Ten years later in 1534, Frenchman Jacques Cartier sailed into the St. Lawrence River and believed that he had discovered a route through America that would lead to China. Cartier’s expedition passed the area of Quebec and was finally stopped at a series of fierce rapids at Montreal. For this reason, the French named these rapids “Lachine Rapids” or “the China Rapids.” Because of Cartier’s failure to locate a passage through to the Orient, the French lost interest in North America for many years. A few small and disorganized French settlement efforts followed in the 1540s and beyond but failed.

> JACQUES MARQUETTE AND LOUIS JOLIET

The earliest Europeans to arrive in North America knew that a great inland waterway flowed through the continent, but it remained unexplored until the arrival of the French. The first Europeans to follow the course of the great Mississippi River were Jacques Marquette and Louis Joliet, explorers from France who came to Quebec for vastly different reasons in the seventeenth century. Marquette was a Jesuit priest whose missionary role led him to New France to learn native languages. Beginning in 1669, Marquette worked in missions near what is today Wisconsin, and it is believed that there he first made the acquaintance of Joliet, who had a successful fur trading business with the natives. In addition, Joliet was an amateur cartographer, and his interest in maps and mapmaking led him to want to explore the regions to the south. In 1672 the French government asked Joliet to take an expedition to explore the northern part of the great river that the natives claimed flowed into a vast body of water (the Gulf of Mexico). Joliet asked Marquette to accompany him as chaplain for the crew. Together these men traveled the Mississippi River as far south as Arkansas before turning northward again. Joliet’s maps were lost in a canoe accident on his return journey to Quebec.

—Cheryl H. White

In Florida, the French settlement of Fort Caroline (near Jacksonville) was established in 1564. This lasted only a year before the Spanish attacked the settlement and killed its inhabitants. Likewise, an effort to settle Sable Island near Nova Scotia as a prison colony failed in 1598, as did a trading outpost near Quebec in 1599. In 1604 the French explorer Samuel Champlain settled a group of men on Port Royal, Nova Scotia. Still, the French efforts in North America had not successfully yielded any of the rich resources that Spain enjoyed in their New World empire, but the French did manage to establish profitable fur trading relationships with many of the natives. This is why Champlain returned to North America in 1608 and established a fur trading outpost at Quebec, which eventually succeeded due to alliances with the natives of

the region. Lake Champlain bears his name, as he made this discovery at the same time he explored the eastern Great Lakes. Champlain was therefore the founder of what would become a prosperous French empire in Canada.

In 1673 a Jesuit named Jacques Marquette and the fur trader Louis Joliet explored the Mississippi River and were followed nine years later by Robert Cavalier, Sieur de La Salle, who is credited with opening up the Mississippi River valley for French claims and settlement. La Salle made several expeditions to the Great Lakes region under the commission of Minister of Finance Jean-Baptiste Colbert and Louis XIV in repeated efforts to locate the passage through to the great ocean of the west and find the gateway to China. These expeditions left behind a network of fortresses that later French settlers would employ in conflicts with the natives and the English. As a result of his exploration southward of the Great Lakes, La Salle claimed all the lands drained by the great river for France, calling it Louisiana, in April 1682 at a great ceremony held in the delta of the Mississippi River. La Salle returned home to great laud and a new commission from the king to serve as governor of the Louisiana colony.

Upon returning to Louisiana in 1684, La Salle's fleet of ships bypassed the mouth of the Mississippi River and ended up in Spanish territory near modern-day Galveston, Texas. La Salle attempted to find his way back to the mouth of the great river but failed. His crew mutinied because of poor conditions and morale, complicated by famine and starvation, and killed La Salle in March 1687. Although tragedy marked the beginning of serious French attempts to successfully plant a thriving colony in southern North America, Louisiana grew because of its strategic control of the main inland waterway of the continent and a great port city that was established at New Orleans. However, the French presence in North America awakened and strengthened old rivalries with the English and led to a series of wars in the eighteenth century. These wars would lead to the temporary transfer of French possessions in North America to the rival colonial powers of the Spanish and the English.

The French approach to colonization has often been cited as a potential reason for the

protracted struggle to make the colonies of North America profitable. The French monarchs of the late sixteenth and early seventeenth centuries had no compelling interest in exploration, and of all the French kings of the era, Louis XIV was the first to take up the active promotion of a New World empire. The ideals were expressed first by the government of Louis XIII and Cardinal Richelieu and further by the rule of Louis XIV to prohibit anyone but Roman Catholics from settling in New France. Further, the colonies of New France in North America did not enjoy the same autonomy and limited self-rule from the Crown as did the English colonies of the Atlantic coast. France transplanted old-style European economic institutions and ideas in the colonies of the New World, a tactic that seldom succeeded. The French colonial model therefore placed the economic control of the territories in the hands of a few proprietors, who often mismanaged land, resources, and relationships for personal gain. The proprietary model made it difficult for the French government to consistently reap financial benefits from its North American colonies.

Dutch Exploration of the New World and Oceania

Since the late Middle Ages, the Dutch were among the commercial and trading leaders of Europe. Because of that distinction, the Dutch were quick to follow the Portuguese and the Spanish in voyages of exploration that held out the promise of new trade markets. Accompanying the Dutch commercial dominance was a corresponding maritime superiority that augmented exploration. This superiority had been gained after years of Dutch seafarers who had sailed with the Portuguese on their voyages to the East and had learned their techniques in navigation and mapmaking. As a result, by the late seventeenth century, which is

often called the Dutch Golden Age, they were unrivaled in sea navigation and commerce and had created new types of sea vessels that required fewer crew. Their first interest overseas was sharing in the spice trade with the Orient, which led to significant Dutch exploration of Oceania and crossing the Pacific beginning in 1598. That year, Olivier van Noort departed from the Netherlands with four ships. By 1600 he crossed the Pacific Ocean to Guam and returned to Rotterdam in 1601 with only one ship remaining and a reduced crew, thus completing the first Dutch circumnavigation of the world.

The Greek philosopher Aristotle postulated that a great southern continent had to exist in order to balance the lands in the north. European expeditions throughout the sixteenth century attempted to discover this continent, but it was never found. In these attempts, the Dutch explorer Willem Janszoon became the first European to explore the coast of Australia in 1606. These expeditions were the result of a growing nationalism that was fueled by the ongoing Dutch rebellion against the Spanish. Coupled with this was the growing weakness of the Portuguese empire, mainly as a result of its incorporation into the Spanish kingdom in 1580. This aggression resulted in the Dutch-Portuguese War in 1602 in which the Dutch hoped to gain control of the lucrative and well-established Portuguese spice trade. Although technically an extension of the Eighty Years' War between Spain and the Dutch, the conflict provided an opportunity for the Dutch to gain a foothold in the overseas imperial work already under way as they attacked Portuguese possessions in South America, Africa, and the Pacific. The war is evidence of the strong global designs of the Dutch as they sought to expand to new markets for popularly traded goods in the new age of mercantilism. Although eventually ousted from Portuguese Africa and Brazil in the 1620s, the Dutch were able to permanently establish their presence in the Pacific by the 1640s. All of this culminated in 1642 with the voyages of Abel Tasman, whose exploration of Australia proved that it was in fact not a part of the mythical Southern Continent. His efforts led to the discovery of New Zealand and Tasmania. He later visited Tonga, Fiji, and the Bismarck Archipelago.

➤ THE DUTCH INFLUENCE ON THE AMERICAS

Even though the Dutch did not successfully realize the promise of an empire in North America, the exploration and colonization efforts as well as the commercial relationships they emphasized did leave a permanent imprint on areas of the North Atlantic and New York. Because the Dutch settlers often used names from their native country to describe settlements, forts, and trading posts, many areas still bear the lasting legacy of the presence of those people. Places in New York such as the Bronx, the Bowery, and Coney Island all reflect the Dutch settlers of the seventeenth century. An interesting example is Hells Gate, New York, the name that now commonly describes a rather treacherous set of rapids in the East River. On a 1639 Dutch map of the river, this region was noted to be “Helle Gadt.” Staten Island has a Dutch name origin, derived from “Staten Eylandt,” so-named in honor of the States General in the Netherlands. The state of Rhode Island also testifies to this influence, as the Dutch named it “Roode Eylante” for the red color of its shoreline. While the Dutch were limited by the outcome of commercial and imperial rivalries with other European nations, there remains proof that the Dutch certainly once shared the same New World hopes.

—Cheryl H. White

Dutch involvement in the direct exploration of North America came about because of an English navigator named Henry Hudson, hired by the Dutch East India Company to find a Northwest Passage to the Orient. He had previously been hired by the Muscovy Company of the Kingdom of England to find a northern route to Asia through the Arctic Circle but had little success. The Dutch hoped that Hudson would be able to succeed in this voyage by going through the Arctic Circle via Russia and reaching Asia that way. Many mariners of the age, Hudson included, believed that by sailing north near the Arctic Circle, they would be able to identify a route to Asia that would avoid the long and difficult sea voyage around the Cape of Good Hope. Hudson left Amsterdam in April 1609 aboard the *Half Moon*, a small vessel with few crew. In the middle of his journey, Hudson made a decision to make a course for North America.

Hudson entered Chesapeake Bay and explored the Delaware River before heading northward and sailing into modern-day New York Harbor and the river that now bears his name. Frustrated and disappointed by the apparent lack of a through waterway, Hudson turned back but recorded the resources and wildlife that he observed. He noted the native populations he observed, their active fur trade, and successful agriculture. His reports circulated throughout the Netherlands when he returned, capturing at least the attention of a few ambitious merchants if not immediately that of the Dutch East India Company.

The report of a thriving fur trade in North America led a series of Dutch merchants to cross the Atlantic to engage the natives. One of the first to follow Hudson to the New World was Adrian Block, who explored the area of the coast of New York in a series of expeditions between 1611 and 1614. An island off the coast that he first charted on a map he drew of the region now bears the name “Block Island,” commemorating this Dutchman’s voyage of exploration. In addition, the map he compiled of the area was the first to name the territory “New Netherland” as well as the first to show Long Island. Following Block’s expedition, he along with his fellow captain Hendrick Christiaensen and 12 other merchants petitioned the States General to obtain exclusive trading rights to New Netherland. Their petition was granted for three years to trade between the 40th and 45th parallels north, and they called their new company the New Netherland Company.

The New Netherland Company was immediately profitable, and many of the merchants excluded from the trading opportunities in North America protested. When it came time for the renewal of the company’s charter in 1618, the exclusive monopoly on trading for a select few Amsterdam merchants ended. An influx of Dutch traders and merchants resulted: men who all pinned their hopes for personal fortune on crossing the Atlantic to New Netherland. These men pushed for the formation of a new company, the Dutch West India Company, to develop and foster trade in the New World. The company received its first charter in 1621 for the express purpose of trade in the Americas and the Caribbean, while

the East India Company continued to operate with its trading privileges restricted to East Asia.

It was through this process that a unique Dutch imprint on North America occurred. Although the primary interest of these men was always trade and commerce, the West India Company decided to establish a colony in North America. In 1624, 30 families left the Dutch Republic and sailed for the new colony aboard a ship aptly named the *New Netherland*. The location of this early Dutch settlement was near modern-day Albany, but others of the group also settled on the island of Manhattan (Fort Amsterdam). Reports of early success in the colony caused others to migrate over the next several years.

Leaders of the Dutch West India Company disagreed about the future of New Netherland, as relations with the natives were often strained and living conditions were difficult for the Dutch settlers. The primary desire had always been to establish profitable commercial relationships in the fur trade over and above the interest in establishing permanent colonies. Many in the company felt that there should be no more Dutch settlement permitted beyond what was necessary to sustain the trade activities with the natives. When missionaries of the Dutch Reformed Church began to arrive in the colony for church planting in New Amsterdam, reports back to the Netherlands provided details about the grim reality of life in the colony.

By the end of the 1630s, the growth of English settlements nearby and the continued hostilities with the natives combined to eclipse the small colony of New Netherland. The outbreaks of the Anglo-Dutch Wars beginning in 1650 led to the eventual surrender of New Amsterdam to the English in 1667. Shortly thereafter, the English renamed the colony New York. These wars effectively ended the colonial presence of the Dutch in North America.

Muslim Explorations

Following the so-called Islamic Golden Age (750–1258), the number of prominent Muslim explorers significantly declined due to the fracturing of the centralized sovereign Abbasid caliphate into a host of decentralized sultanates (e.g., Ottoman, Safavid, and Mughal) with limited authority. Nevertheless, it would be inaccurate to conclude that Muslim exploration ceased at the close of the medieval period. Three early modern Muslim explorers made significant contributions to geographical knowledge: Hadji Muhiddin Piri ibn Hadji Mehmed, better known by the shortened Piri Reis (1470–1555); al-Hasan ibn Muhammad al-Wazzan al-Fasi, typically designated by the Latinized monicker Joannes Leo Africanus (1494–1554); and Evliya Çelebi (1611–1682).

Piri Reis (*reis* is Arabic for “captain”) was an Ottoman Turkish explorer and cartographer whose travels were made possible by military expeditions. Joining the Ottoman navy at age 11, he took part in many battles against the navies of Spain, Genoa, and Venice and accompanied his uncle Kemal Reis, a notable seafarer, on several voyages. The destinations of these voyages were unknown until 1929, when historians discovered a remarkable map that Piri drew in 1513 showing the western coast of Africa, the eastern coast of South America, and the northern coast of Antarctica. The map’s level of accuracy in the positioning and the proportions of these continents would remain unparalleled for centuries to come. But most stunning about this map is that on the traditional dating, Antarctica was not discovered until 1820; nonetheless, the depiction of its coastline with nearly perfect accuracy permits little doubt that Piri observed it firsthand and hence was in fact the true discoverer of Antarctica. Moreover, his virtually flawless rendering of the South American coastline displaying features absent from all previous maps, including those of Columbus, render it highly

▶ JOANNES LEO AFRICANUS AND HIS HISTORY OF AFRICA

In 1600, Cambridge linguist John Pory teamed with London publisher George Bishop to produce the first English translation of Joannes Leo Africanus’s *Della descrittione dell’Africa et delle cose notabili cheiui sono*. The following quotation gives the flavor of Joannes’s work:

“The Arabians which inhabite in Barbarie or vpon the coast of the Mediterran sea, are greatly addicted vnto the studie of good artes and sciences: and those things which concerne their law and religion are esteemed by them in the first place. Moreouer they haue beene heretofore most studious of the Mathematiques, of Philosophie, and of Astrologie: but these artes (as it is aforesaid) were fower hundred yeeres agoe, vtterly destroyed and taken away by the chiefe professors of their lawe. The inhabitants of the cities doe most religiously obserue and reuerence those things which appertaine vnto their religion: yea they honour those doctours and priests, of whom

they learne their law, as if they were petie-gods. Their Churches they frequent verie diligently, to the ende they may repeat certaine prescript and formal prayers; most superstitiously perswading theselues that the same day wherein they make their praiers, it is not lawfull for them to wash certaine of their members, when as at other times they will wash their whole bodies. Whereof we will (by Gods helpe) discourse more at large in the second Booke of this present treatise, when we shall fall into the mentioning of Mahumet and his religion. Moreouer those which inhabite Barbarie are of great cunning & dexteritie for building & for mathematicall inuentions, which a man may easily coniecture by their artificiall workes.”

probable that Piri explored the eastern edge of South America decades after it was first discovered. Substantiating these hypotheses are Piri's descriptions of the three continents in his 1521 *Kitab-i Babriye (Book of Navigation)*, which bear all the traces of eyewitness reminiscence. The *Kitab* includes not only detailed information on the key ports, bays, gulfs, capes, peninsulas, islands, and straits of these regions but also data on the natives of each South American culture along that continent's eastern coast.

Born in Granada and educated at the University of Al Karaouine in Fez, Joannes Leo Africanus was a Moorish explorer and diplomat. In 1510 he traveled to Timbuktu on a diplomatic mission to the Maghreb, then part of the Songhai empire. After being captured by Spanish corsairs and presented to Pope Leo X in 1520, Joannes received the papal blessing and was released due to the curia's fear that the Turkish forces might otherwise invade Sicily and southern Italy. He then left Rome and extensively explored northern Africa for the next six years, at the end of those journeys composing his magnum opus, *Della descrizione dell'Africa et delle cose notabili cheui sono (History and Description of Africa and of the Notable Things Contained Therein)*. Foremost among its accounts are those of Hausaland, Bornu, the Sahara, and Timbuktu, the latter of which was a thriving metropolis vitalized by traders in African products, gold, printed cottons, slaves, and books. Of historical worth is Joannes's rare portrait of mountain culture and Berber culture as the two competed for power in Morocco.

The Turkish traveler Evliya Çelebi was an adherent of Sufism who journeyed from his native Istanbul throughout eastern Europe, the Mediterranean basin, Eurasia, and the Middle East. His extensive notes on the buildings, markets, customs, and cultures from each locale visited from 1640 to 1672 formed a ten-volume collection called the *Seyahatname (Book of Travels)*. The enduring legacy of this collection is its value as the best guide to the languages, cultural distinctions, and lifestyle of the Ottoman empire during the early modern period. Having collected specimens of over 30 Turkish dialects and numerous languages from the places he traveled, Çelebi foreshadowed the theories of modern linguists by pointing out

the similarities between several German and Persian words, thus suggesting their common Indo-European heritage. Extremely significant are Çelebi's notes on Kurdish in eastern Anatolia and the only extant samples of written Ubykh before modern times. The ten volumes of the *Seyahatname* narrate the following explorations: (1) Istanbul and the surrounding areas (1630); (2) Anatolia, the Caucasus, Crete, and Azerbaijan (1640); (3) Syria, Palestine, Kurdistan, Armenia, and Rumelia (1648); (4) eastern Anatolia, Iraq, and Iran (1655); (5) Russia and the Balkans (1656); (6) Hungary (1663–1664); (7) Austria, the Crimea, and the Caucasus (1664); (8) Greece, the Crimea, and Rumelia (1667–1670); (9) Mecca (1671); and (10) Egypt and the Sudan (1672).

Russian Exploration of Siberia and Asia

The first Russians to expand into regions east of what later became known as the European Russian heartland were Novgorodian merchant-princes, who in the late eleventh century pushed into the northern lands on both sides of the Urals in search of lucrative furs. As these merchants encountered opposition from the indigenous inhabitants, they inevitably called in Novgorodian troops to pacify hostile semisedentary tribes. Though the Novgorodians were often defeated (as by the Yugra in 1193), by 1264 Novgorodian chroniclers were listing Yugara lands west of the Urals as Novgorodian territory. Accordingly, even from the beginning, it becomes impossible to separate the Russian exploration of Siberia and Asia from the process of conquest.

► EARLY RUSSIAN CONTACTS WITH CHINA AND JAPAN

Russian Cossacks led by Yerofey Khabarov first encountered serious opposition to Russian eastern expansion in 1650 when they ventured south into the Amur delta and ran into forces dispatched by the Qing empire of China. The Russian government responded to Chinese invitations to clearly define the border, and on August 27, 1689, representatives of the two governments concluded a treaty at the Siberian town of Nerchinsk. This treaty gave up Russian claims to any Amur territory but established official trade between the two countries. This trade, eventually consisting primarily of tea, remained extremely lucrative for the Russian government well into the nineteenth century.

Russia was the western country closest to Japan and consistently tried to open trade and establish diplomatic relations with the Tokugawa government. By the early 1700s, Russian expeditions, commissioned by tsars, began to reach Japanese waters. Increasing numbers of Japanese castaways began washing up on Russian shores, and their enthusiastic descriptions of Japanese economic life made trade seem very attractive to Russian officials, especially as it could feed eastern Siberia and Alaska. However, though an expedition led by Adam Laxman (1792–1793) was favorably received, it failed in getting the Tokugawa government of Edo to establish diplomatic relations.

—Viktor Shmagin

The Mongol subjugation of most of Kievan Rus in 1237–1240 and the establishment of the Golden Horde as a tribute-collecting successor state halted full-scale Russian expansion into Siberia for three centuries. However, the process was dramatically restarted following the conquest by Ivan IV (Ivan the Terrible, r. 1533–1584) of the Mongol successor states of Kazan (1552) and Astrakhan (1556). Muscovite tsars, the new overlords of Russia, had opened the whole of Siberia to Russian penetration by absorbing the competing Mongol successor states of the Volga. As no other power was strong enough to stop their drive eastward, Russian explorers and trappers quickly reached the Pacific Ocean by 1649.

Initial Russian expeditions east could be organized by the state but were most often put together on the private initiative of Cossacks, fur trappers, criminals, and other adventurers, which gave them a heavy mercenary character. They were heavily armed and moved quickly over the extensive Siberian river network, carrying their light boats across portages when necessary. Typical of such expeditions was that of Yermak Timofeevich, a Cossack who conquered the Sibir khanate in the 1580s with 1,000 mercenaries (composed of Cossacks, Tatars, even some Germans) and, with the financial backing of the wealthy Stroganoff family, went on to monopolize the fur trade in the region.

The remoteness of the Russian state and its preoccupation with European affairs ensured a great degree of latitude in decision making for these expeditions and encouraged their restless members to settle in Siberia. This prospect was immensely attractive for people on the margins of Russian society, especially for semi-independent, culturally distinct groups like the Cossacks, who practiced a form of frontier warrior-democracy. To be sure, the state eventually followed in the wake of Russian conquest. The Department of Siberian Affairs was established in 1637, and until the mid-eighteenth century it was chiefly concerned with the details of the fur trade. Ironically, this government presence, although weak, was brought to Siberia by the very people who sought to escape it in the first place.

The official government policy toward conquered peoples was to demand tribute in the form of beaver pelts, known as the *yesak*. Upon paying, Kamchagals, Chukchi, and other Siberian peoples were regarded as Russian subjects, entitled to Russian protection. Conversion to Russian Orthodoxy was only required upon marriage, which happened often, as the great majority of Russians who participated in the initial conquests were men. This relatively relaxed official policy should not lead us to assume that relations between Russians and Siberians were entirely amicable following the conquest. Though the official *yesak* was light, corrupt officials and even

armed settlers often turned to extortion, causing many indigenous populations to flee. Ambushes and raids were also common, and several organized rebellions also took place, including a major one by the Kamchagals in 1730.

Large peasant migrations from European Russia often followed times of famine or dislocation, as during the Time of Troubles (1598–1613). A further impetus for peasants to flee came with the gradual introduction of serfdom, complete by 1658. Though western and southern Siberia contained some land suitable for cultivation, the Russian Far Eastern settlements lacked an agricultural heartland. The settlements thus depended on foodstuffs imported overland from European Russia and long remained sparsely settled. During the 1850s, the governor-general of eastern Siberia, Nikolay Muraviev, changed the situation by occupying the rich Amur basin and forced a weakened China to cede this territory via the Treaty of Aigun (1858).

The Russian government became increasingly interested in reinforcing Siberia militarily and systematically exploiting Siberian resources other than fur. These two objectives were

made possible by the construction of the Trans-Siberian Railroad, which became operational by 1905. The Russian government was also greatly interested in obtaining an ice-free Pacific port. Vladivostok, founded in 1860, became the primary Russian port in the region, but the fact that it still froze over in the winter forced future Russian leaders to look south, which eventually brought about war with Japan in 1904–1905.

■ Introduction: New Channels for Cultural Contact and Exchange

The early modern period was a time of unprecedented cultural contact. The conquests of the burgeoning empires of the period, including western European, Russian, Islamic, and East Asian states, the opening of trans-oceanic trade and migration, the expansion of Islam and Christianity, and the hostility of many societies to religious minorities all resulted in the movement of individuals and populations on a global scale. Europeans became a presence in the Indian Ocean and even as far as Japan, while Eurasian and African peoples established themselves in the Americas, not only the European invaders and their African slaves but also the Chinese commercial diaspora, which established itself as far away from China as Mexico City. (The converse was not the case, and Native Americans

did not form any successful communities outside the Americas.) Even the simple awareness of the size and diversity of the world and its peoples could have profound cultural effects.

Not all societies opened themselves to the new cultural contacts. After a period of great cultural openness in the sixteenth century, Japan became the most famous example of a country that closed itself in the seventeenth century, although Korea, the “Hermit Kingdom,” was even more successful. China also turned away from much cultural contact, although its continental position did not allow it to isolate itself as successfully as the smaller states of East Asia. Persia’s unique brand of Shia Islamic government also worked to isolate the country, while the Sunni Ottoman empire, with its numerous

religious minorities and the welcome it extended to Jewish refugees from Europe, was a relatively open Islamic society.

Cultural contact and exchange could take many forms. Some cases often resulted in the mere imposition of one culture on another, often accompanied by the replacement of one population by another. European-based cultures and European-descended peoples simply displaced Native American cultures through much of North America through violence. Native languages were replaced by European ones, and native religion was replaced by Christianity. In other areas new and old cultures coexisted although deeply affected by the societies in which they lived. Jews also preserved their own unique customs, languages, and religion as they traveled between the Islamic and Christian worlds. Sometimes cultural contact resulted in the creation of new syncretic cultures. For example, Native American cultures in the Spanish-American empire and French Canada were deeply shaped by Christianity while retaining many indigenous characteristics.

Short-distance migration as well as long-distance migration could shape culture, and many migrants merely moved to the next country or the next island over rather than crossing the globe. Cities in particular were cultural melting pots, attracting migrants from near and far and often putting them in close juxtaposition. Commodities as well as people spread new cultures. European culture was fundamentally changed by the great availability of East Asian luxury products including spices, silks, and porcelains brought by Portuguese and Dutch traders as well as American products such as chocolate and tobacco. European and colonial manufactured goods such as copper pots, blankets, and metal needles greatly altered the culture of Native Americans.

—William E. Burns

Dhimmis, “People of the Book”—Christian and Jewish Traders in the Ottoman Empire

The Ottoman empire is considered by some historians to have been the most religiously tolerant state in the world throughout its history. This was due to legal and practical necessity in contrast with the ideals of the Enlightenment that finally

awakened a sense of tolerance in Europe after centuries of religious strife. In addition, non-Muslims were considered by state authorities to be crucial to the economic prosperity of the empire.

From the practical perspective, the Ottoman empire stretched across three continents and contained large numbers of Jews and Christians in addition to Muslims. Yet the divisions in the population into three religious categories were far more complex, as among the Christians there were various subdivisions in the rite and ritual that viewed each other with some suspicion. These included, in no particular order, Coptic Christians in Egypt, the Greek Orthodox in Europe and Anatolia, Armenian Christians, the Syrian Orthodox, Maronites, and some Catholics, among others. Divisions also existed among the Jewish population particularly as Sephardic Jews emigrated from Spain to escape the Spanish Inquisition. With this wide range of ethnic and religious diversity in the Ottoman domains, one could not hope to maintain stability by oppressing differing religious beliefs.

From a legal perspective, an Islamic ruler was compelled by Sharia, or Islamic law, to protect the religious rights of the *ahl al-dhimmi*, or People of the Book, meaning a religion that had received the revelations of God but who had not accepted the teachings of Muhammad. Muslim rulers historically have considered Jews and Christians as People of the Book. They were allowed to practice their own faith as long as they accepted Muslim rule and paid an additional head tax known as the *jizya*. Furthermore, they were not allowed to serve in the military or hold positions in the government, although exceptions did occur. Their rights did fluctuate depending on the ruler and region of the empire. The non-Muslims were then governed through a semiautonomous millet system.

Of particular importance were the Jewish, Greek, and Armenian merchants. Although the Jews, both Ashkenazim and Sephardim, belonged to their own millets, as did the Armenians, both were spread throughout the empire and thus allowed trade networks across the empire and even beyond. Indeed, the Jewish and Armenian Christian trade networks extended not only into both western and eastern Europe but also eastward into Persia, India, and even

THE MILLET SYSTEM

To better govern the various religious groups within the empire, the Ottomans devised the *millet* (nation) system. The millets continued many preexisting practices but also formalized them within the Ottoman system of governance. Each religious denomination was a millet. The millets supervised the education, welfare, and legal system of their respective group. The leaders of the millet, usually the highest-ranking religious official along with other notables, represented the people in interactions with the Ottoman government. Thus, they were more or less left to their own devices as long as they paid their taxes and did not cause trouble for the state. Indeed, each group was governed by its own personal law rather than *sharia*, or Islamic law, although the latter was used in interreligious disputes involving Muslims.

The millets varied considerably in terms of size and composition. Although the millet system did not consist of a series of cantons, many people of the same faith did tend to live in the same area. A millet, however, could be spread throughout the empire. For instance, the Greek Orthodox millet, led by the patriarch in Istanbul, consisted of all who followed the Greek Orthodox rite. This included not only Greeks but also various Slavic groups and even Arabs who practiced the Greek-Orthodox religion. Thus, on the census roles all of these groups were listed as Greeks. For the Ottomans, as it had been in much of the Middle East for centuries, religious identity trumped ethnicity.

—Timothy May

China. The Ottoman government encouraged the development of these trade networks. By 1484 they excluded foreigners from the Black Sea and thus allowed Ottoman subjects surrounding the sea (mostly Jews and Christians) to fill the vacuum caused by the expulsion of the Italian merchants. By the seventeenth century, the roles of *dhimmis* who were engaged in commerce became a bit more regular. Jews dominated tax-farming opportunities, while Greeks controlled much of the trade within the empire and Armenians handled most of the international trade for the empire, including the lucrative silk trade through Persia. Although these categories existed, exactly who dominated what

aspect of trade fluctuated over the centuries. For instance, by the eighteenth century Greeks dominated most of the European international trade. Although Muslims also participated in the trade and the economy at all levels, an increasing portion of it fell into the hands of the *dhimmis*, who because of their religious affiliations often developed better relations with European powers, particularly since the seventeenth century.

Indeed, in most of the port cities, local Armenians, Greeks, and Jews handled most of the commerce coming from Europe. The amount of trade that they controlled also began to alter their relations with the empire as the millet system broke down during the nineteenth century, largely due to European intervention. As the Ottoman military became less dominant in the region, European powers gradually gained concessions in trade, territory, and sometimes authority within the empire by the nineteenth century. For assisting the Ottomans against internal rebellion, the Russians gained the right to intervene on behalf of the Greek Orthodox millet, whereas the French gained the right to intervene on behalf of Catholics and the Maronites (who recognized the pope) in Lebanon. Their intervention, while not the sole cause, also caused an increase in religious strife as the traditional system began to fray.

Island Migration—Southwestern Indian Ocean Patterns

When the Portuguese sailed into the Indian Ocean at the end of the fifteenth century, they encountered islands both inhabited and

uninhabited. Madagascar and the four Comoros Islands, which lie about midway between northern Madagascar and the coast of Africa, had already been inhabited by Malayo-Polynesian and African settlers for about 1,000 years. The other major archipelagoes of the southwestern Indian Ocean would remain uninhabited for some time: the Mascarenes—including Mauritius and La Réunion, due east of Madagascar—until the seventeenth century and the Seychelles, to the northeast, until the late eighteenth century.

The Merina descendants of the original Malayo-Polynesian settlers of Madagascar had retreated to the interior highlands, while the coasts were occupied by Africans with strong ties to the Swahili coast of East Africa (modern Tanzania and Kenya). In the Comoros there was a comparable differentiation between Africans, who lived in the interior, and Arab traders, who dominated the coasts and were also in regular contact with East Africa as well as Arabia and the Persian Gulf. The European penetration of the Indian Ocean at the end of the fifteenth century signaled the start of a new phase in the history of the islands, although the transformation was gradual. As the *Estado da India* spread its monopolistic practices over the trade between East Africa and India, many Muslim merchants and their families fled East Africa for the Comoros and Madagascar. According to tradition, Persian immigrants from Shiraz reached the islands at about the same time and established a collection of sultanates on the islands that became the focus of increasing attention for merchants, especially slave traders, from Arabia, the Persian Gulf, and western India. Only on Mayotte were Malayo-Polynesians in the majority. This remained true through the periods of colonization and decolonization, and when the Union of Comoros Islands achieved independence in 1975, the people of Mayotte elected to remain a territorial collectivity of France.

Madagascar played only a marginal role in the trade of the Indian Ocean. It was too far north for European ships bound for India or Batavia, and the Comoros were on the way from East Africa to the Arabian Peninsula or the Persian Gulf. The Portuguese brought Malagasy captives to Lisbon in 1506, but apart from three desultory expeditions to the island between 1506 and

1521, few Portuguese visited the island except for castaways and their would-be rescuers. Despite the lack of official Portuguese interest in trading with the islands, the extortionate policies of Portuguese Crown officials in East Africa drove many ordinary Portuguese into unofficial trade with the islands, and they were serving as middlemen in the Comorian slave trade by mid-century. When Goa dispatched a survey expedition to the island in 1613, the authorities knew enough to embark with the expedition interpreters who were competent in Arabic, Kiswahili, and its Madagascar variant, and Malagasy. As elsewhere in the Indian Ocean, they seized a local prince to teach him Portuguese and the Christian faith in Goa so that he could proselytize among his own people, a plan that met with only slight success.

The English, Dutch, and French all became interested in Madagascar at the start of the seventeenth century, but their efforts to colonize the island in the 1640s met with failure. The English and Dutch settlements lasted only two or three years, but the French held on at Fort Dauphin in the southeast from 1642 to 1674, after which they turned their attention to the Mascarenes and the Indian subcontinent. Although the European India companies lost interest in Madagascar, at the end of the century it became a major rendezvous for pirates and slave traders from the Americas. The island was well positioned for attacks on shipping in the western Indian Ocean from the Red Sea to India. Despite the great distances involved, the growing demand for slaves in Brazil and British America made it worthwhile for traders to purchase slaves in Madagascar and the Comoros, where they cost one-sixth to one-eighth what they did in West Africa.

The Indian Ocean slave trade received a further boost following the French development of the Mascarene Islands, principally La Réunion, 435 miles (700 kilometers) east of Madagascar, and Mauritius, about 120 miles (200 kilometers) northeast of La Réunion. Visited by Muslim sailors in the tenth century and the Portuguese at the start of the sixteenth century, the Mascarenes remained uninhabited until 1638, when the Dutch deemed it expedient to establish a presence on Mauritius to prevent the English or French from doing so. Dutch attempts to farm the island using

European crops and techniques failed, although their Malagasy slaves were more successful. Nonetheless, they abandoned Mauritius from 1658 to 1664 and again for good in 1710. Their most significant accomplishment during their occupation was to make the dodo extinct.

Having settled La Réunion (which they originally called Ile de Bourbon) from Madagascar in 1665, the French were poised to replace the Dutch on Mauritius, which they occupied in 1721 and renamed Ile de France. Following the establishment of plantations for coffee, sugar, spices, vanilla, and coconut on Ile de France, the slave population grew from 600 to 3,000 between 1734 and 1739. By the end of the eighteenth century the population of Ile de France alone was nearly 60,000, of which about 50,000 were slaves, 6,000 were Europeans, and fewer than 4,000 were free Indians. (After the British seized the island during the Napoleonic Wars in the early nineteenth century, they introduced nearly 500,000 Indian indentured workers, which is what gives the island its pronounced Indian influence today.)

The last significant archipelago in the southwestern Indian Ocean is that of the Seychelles, a group of about 115 islands centered about 680 miles (1,100 kilometers) northeast of Madagascar. It is more than likely that Malay, Arab, and Indian navigators came across the Seychelles in traversing the Indian Ocean, but the islands were inhospitable, and the presence of reefs discouraged interest in them. The French finally claimed them during the Seven Years' War with Britain (1756–1763), and the first settlers arrived from Mauritius, with slaves, in 1770.

Population Movements in Dar-es-Salaam—Islamic Migrations

One of the remarkable features of the age of first global contact was the spread of Islam through the *umma*, or community of practitioners—merchants, missionaries, soldiers, military leaders, royalty, slaves, artisans, and scholars—expanding the boundaries of Dar-es-Salaam. The migration of Muslims, which began with the outreach of Islam beyond the Arabian Peninsula during the seventh century, took on global proportions with the opening of the New World in the late fifteenth century. By the early seventh century, Muslims had already established settled communities from the Iberian Peninsula to the Indian subcontinent that included millions of adherents. However, the three centuries following European colonialism in the Western Hemisphere also saw hundreds of thousands of Muslims enslaved in West Africa and forcibly transported to South America, the Caribbean, and North America, where they worked on plantations, in mines, as domestic servants, and as artisans. Tens of thousands of Muslims in the Americas gained their freedom through force of arms, manumission, and flight, forming elements of the first free black communities in the West, but the vast majority of Muslims in the world were free subjects under one or another imperial rule.

Traveling by sea via the southwestern monsoon wind currents and predating the spread of Islam to the New World via the Atlantic slave trade was the Indian Ocean slave trade of both Muslims and non-Muslims alike. The trade fueled the migration of war captives and indebted persons to central and southern India and Sri Lanka and farther to the East. Extensive trade networks established by North African and Middle Eastern Muslim merchants in the Eastern Hemisphere further developed overland routes westward and to the East, bringing Islamic scholars, Sufi teachers, and skilled workers to the farthest reaches of Eurasia and Africa. As a result, between the tenth and eighteenth centuries Islamic communities, composed of old and

new converts, nearly doubled in size. The Chinese admiral Zheng (1371–1433) exemplified the important role of Muslims in Eastern imperial realms. During the early fifteenth century, the Muslim admiral led seven seafaring expeditions from Ming China, one of which reached the East African coast.

As they spread, Muslim populations absorbed traditions of the two other major monotheistic religions of the Old World, Judaism and Christianity, as well as assimilating practices and beliefs from Buddhist, Hindu, and other polytheistic and animistic faiths. The cultural synthesis produced by the resulting mixture of people and their traditions was reflected in the increasingly multicultural and multiracial communities from Europe to China. By the sixteenth century, several Islamic empires—the Songhai, Ottoman, Safavid, and Mughal empires—would come to command far-reaching influence in North and West Africa, the Middle East, and South Asia.

In the eastern Mediterranean, the Muslim-based Ottoman empire took over Constantinople (located in present-day Turkey) in 1453, renaming the city Istanbul and ending the reign of the Christian-based Byzantine empire; by the eighteenth century Ottoman rulers controlled much of the Balkan Peninsula, the Arabian world, and North Africa. Beginning 500 years earlier in sub-Saharan western Africa, the Islamized state of Mali ruled over populations that practiced essentially indigenous forms of religion but were nevertheless tied to the wider Muslim world through culture and commerce, driven by the trade in gold and salt. The Mali king Mansa Musa, known for his extraordinary wealth in gold, made a pilgrimage to Mecca in 1324 and returned with hundreds of architects, scholars, and artists to western Africa. Consequently, a flourishing of Muslim culture in West Africa centered at Timbuktu soon followed. During the sixteenth century, Mali would be overtaken by the distinctly Muslim Songhai empire, which established itself as the dominant political and economic force in the region, converting ever-larger numbers of West and central West Africans to Islam.

Several centuries earlier, Mongols from across the Asian steppe swept into the Middle

East, destroying Muslim societies while in the process introducing their own traditions into the region. Mongols would rule the area from the Sinai desert to northeastern India through the early fourteenth century. However, they too eventually converted to Islam, becoming known as the Il-Khanids, one of four subdivisions of the Mongol empire. Muslims initially entered South Asia (present-day Pakistan and India) through the Indus River valley and began to gain political power in the early thirteenth century. Islamic sultanates of the era were in turn supplanted by the Mughal empire beginning in 1526, which dominated much of northern and central India into the eighteenth century, mixing Hindu and Jain traditions into their architecture and arts. In Agra, the Taj Mahal, completed in 1648, stood as one of hundreds of monuments exemplifying the splendor of Muslim imperial rule across Eurasia and North Africa, with meticulously built mosques, mausoleums, palaces, and commercial centers. Farther to the east beginning in the twelfth century, Islam would also spread to the Malay world. Starting in northern Sumatra, Muslim kingdoms were established in Java and mainland Malaysia, making Islam the majority religion in many of these areas as well.

In 1502 Persia (present-day Iran), long an important part of the Sunni world with a Shia minority, was overtaken by a popular group called the Safavids. The Safavid empire attracted Shia scholars from the Arab world, creating a lasting Shia influence in this part of the Middle East. Persia became a predominantly Shia region in this period and has remained so to the present day. The Safavids would establish a powerful state for over two centuries and ushered in a flowering of the arts and sciences in the region. Their capital, Isfahan, became one of the most exquisite cities in the world, known for its blue-tiled mosques. In 1736 an invasion by the Afghani put an end to Safavid rule; Islam, as in other parts, nevertheless continued as the primary religious and cultural influence in the region.

Muslims entered East Africa in the eighth century, but their social and economic influence remained largely confined to coastal communities, where trading ships traveled back and forth from the Arabian Peninsula. Over the course of several centuries, the Sudan and Somaliland

became Islamized in eastern Africa, with Harar becoming a seat of Muslim scholarship. Gradually Islam as a cultural, economic, and political force made its way farther inland and southward, with conversion to Islam being led by those who communicated with local rulers; many who converted were also family members of Arab and Swahili merchants. In some parts of eastern Africa matrilineal social principles—for instance, among the Yao and Makuea—created tensions with Islam’s patrilineal order. But whether in West, central West, or East Africa, pre-Islamic religious elements would persist as Islam was largely incorporated into existing societies.

To the west and across the Atlantic, by the eighteenth century there were many thousands of African Muslims from Senegambia, Sierra Leone, the Gold Coast, and coastal Benin working as slaves on plantations in the Americas. Distanced from their multiple heritage and places of origin, most enslaved Muslims in the New World lost a great deal of their Islamic identity. Many were forced to assimilate the dominant religious and social practices of Protestant Christian British North America and Catholic Spanish and Portuguese South America. Yet many Muslims were able to maintain ties to their faith. One of several extraordinary cases is that of Ayuba Suleiman Diallo, also known as Job Ben Solomon (1701–1773). Ayuba, who arrived in Annapolis, Maryland, as a slave in 1731, turns out to have been the son of a king in the Senegal River region. His Arabic writing abilities so impressed a lawyer that he purchased the princely slave’s freedom. The now freedman would go on to write all 6,321 verses of the Quran three times from memory. He traveled to England, where he became a renowned linguist before returning to his native West Africa.

The degree to which Muslims were able to practice their religion varied from place to place, creating a range of cultures in the process. By the late eighteenth century, settled and migrant communities of the Islamic faith formed vibrant parts of virtually every major urban community in the world outside of Christian-dominated Europe, including large swaths of rural areas in Africa and Asia.

Island Migration— Caribbean Ocean Patterns

Migration—both free and forced—has strongly influenced the making of Caribbean history. The first inhabitants of the region were three indigenous groups: the Guanahatabeys, the Tainos, and the Caribs. The Guanahatabeys were perhaps the first indigenous people to arrive in the Caribbean, migrating from South America. They were forced back to western Cuba by the Tainos, who settled mainly in the Greater Antilles. The Caribs, also from South America, were the final group to migrate to the Caribbean and established their residence in the Lesser Antilles. The population of the Caribbean on the eve of European contact in 1492 is estimated at 775,000 inhabitants.

Since prehistoric times, indigenous populations of the Caribbean had migrated over short and long distances to conduct trade. Archaeological studies demonstrate that semiprecious stones, which were not native to a particular island, were found there as a result of commodity exchange. An example of long-distance trade is the discovery of turquoise beads in Montserrat. Turquoise is not native to the Caribbean islands but is found in South America, which shows that native Caribbean peoples may have traveled long distances to collect the stone. Moreover, according to anthropologist David R. Watters, this evidence of long-distance trade may demonstrate that the indigenous peoples who came from South America and later moved to the Lesser Antilles traveled back to their native land instead of abandoning it completely.

Europeans began their colonization of the Americas in the late fifteenth century. Approximately 1.4 million Europeans journeyed to the New World during 1500–1783. The British represented the largest group of European migrants, totaling 722,000 between 1607 and 1780. Relatively few Europeans settled in the Caribbean, however. With respect to the Spanish Antilles, some 12,000 Spaniards immigrated to Hispaniola alone by the early sixteenth century. Nonetheless, as of 1570 there were only about 7,500 Spaniards in the Caribbean due to Spanish immigration to other parts of the empire and rapid indigenous depopulation. The French, British, and Dutch Antilles also received few European colonists. In 1789 the French formed only 8 percent of the population in Saint Domingue and 12 percent of the population in Guadeloupe. By the nineteenth century, Europeans in Barbados and Surinam totaled 15 percent and 4 percent of their respective populations.

Forced migration of indigenous and African slaves to the Caribbean occurred on a large scale in the early modern era. As the numbers of Tainos in Hispaniola, Cuba, and Puerto Rico dropped rapidly in the sixteenth century due to the spread of European and African diseases, malnutrition, and overwork in the gold mines and on agricultural estates, Spaniards began to conduct indigenous slave raids in other areas of the Caribbean and Central America to replace the dwindling workforce in the Greater Antilles. These slave raids only increased indigenous depopulation in the Americas, particularly in the Caribbean.

The decline of the aboriginal population and the rise of the plantation complex in the West Indies served as the impetus for the large-scale importation of African slaves. Of the 11 million slaves who were forced to migrate to the Americas from the fifteenth to the nineteenth centuries, approximately half of them were destined for the Caribbean, which made Africans the largest group of migrants to the region in the early modern era. The importation of slaves to the Caribbean rose significantly from the mid-seventeenth through the eighteenth centuries due to the increased demand for labor for the production of cash crops, particularly sugar. Some 325,000 African slaves migrated to the Americas

THE TAINOS

The ancestors of the Tainos originated from South America. At the time of the Spanish arrival to the Caribbean in the late fifteenth century, the Tainos resided in the Virgin Islands, the Leeward Islands, the Greater Antilles, and the Bahamas. They had local and regional chiefdoms, and their society included classes of nobility and commoners. In addition to fishing and hunting, the Tainos cultivated cassava, maize, sweet potatoes, legumes, peppers, tropical fruits, and tobacco. They also engaged in regional maritime trade and produced pottery, cotton cloth, and objects carved from stone and wood. The Spanish conquest led some Tainos to escape to the Lesser Antilles, which Europeans did not occupy until the seventeenth century. Although this indigenous group has vanished from the Caribbean, people of partial Taino heritage continue to inhabit the Greater Antilles due to the intermarriage between Tainos and Spaniards in the sixteenth century.

—Vanessa M. Ziegler

in the sixteenth century, headed primarily for the Spanish American colonies and Brazil. By the advent of the eighteenth century, British Caribbean planters had purchased 263,000 slaves, while French Antillean producers had bought 156,000 slaves. Finally, by 1700 the Dutch Caribbean had imported 40,000 slaves.

African slaves established maroon communities to escape the brutal conditions of forced labor on Caribbean plantations. The flight of slaves to maroon villages served as a form of internal migration. The longevity of runaway communities rested on effective leadership and military defense. Maroons in Jamaica made two peace pacts with British forces in the eighteenth century. In addition, the resilience of maroon communities depended on the remoteness of a community's location. Thus, maroon villages were usually established in the mountains and forested regions of the Caribbean. Afro-Caribbean migration away from the islands seldom occurred until the abolition of slavery in the nineteenth century.

Jewish Expulsions and Migrations

The incidence of expulsions and migrations of European Jewry into central Europe and the Mediterranean littoral in the period from 1450 to 1770, most notably the Spanish expulsion of 1492, followed the trajectory of centuries of religious anti-Semitism that characterized medieval Europe. However, the expulsions of Jews during this period were shaped more by either Catholic and Protestant attempts to control the confessional preferences of their respective realms amid the social tumults of the Protestant Reformation, the Catholic Counter-Reformation, and the Wars of Religion (particularly the Thirty Years' War). Despite these episodes of widespread persecution and expulsions, Jewish migrants were able to find refuge outside their former homelands in relatively more tolerant host countries. Moreover, regardless of the large numbers of Jewish expellees and resultant migration patterns, much more effort was spent persecuting heretics, witches, or recent converts (such as *conversos* in Spain) by ecclesiastical and state authorities.

Prior Jewish expulsions prompted by European monarchs, particularly by Edward I of England (1290) and Louis X of France (1306), were

part of their efforts in centralizing their power. These removals of Jewish populations, while related to eschatological Christian worldviews that regarded Jews as a manifestation of evil guilty of corrupting Gentile society, were more of an assertion of royal control over what were deemed vulnerable scapegoat populations. Moreover, accusations against Jewish populations of blood libel (human sacrifice, typically children, for the use of their blood for religious rituals), the poisoning of wells, and *maleficium* (malevolent sorcery), particularly amid outbreaks of the Black Death, also prompted Jewish migration in the late Middle Ages. However, conversion to Christianity was also seen by a large number of Jews as a means of stemming violence and social discrimination by Christians.

Expulsions of Jews from various realms of the Holy Roman Empire occurred early in this period, organized and coordinated at top and local levels of government. Expulsions proceeded in Upper Bavaria (1442), Lower Bavaria (1450), Mecklenburg (1492), Pomerania (1493), Lower Austria, Carinthia, and Styria (1496), and these were typically decreed by representative institutions at the regional level. Major cities, such as Vienna (1421), Cologne (1424), Dresden (1430), Augsburg (1440), Erfurt (1458), Mainz (1470), Salzburg (1498), Nuremberg (1499), and Ulm (1499), also expelled their Jewish populations at the bequest of local authorities, often to the displeasure of the local prince and the Holy Roman emperor. The Habsburg dynasty and other high-ranking aristocratic families relied on Jewish communities for financial assistance. Therefore, Jewish expulsions were not in their best interests but were nonetheless within the rights and privileges of the individual polities of the empire. Many of these Jewish migrants went to other German cities and elsewhere in eastern Europe into relatively more tolerant regions. Moreover, while these expulsions tapered off, they resumed later in the sixteenth century with the religious fervor unleashed by the Protestant Reformation by both religious dissidents and Catholics attempting to demarcate their ecclesiastical and political divisions within the Holy Roman Empire.

As the Spanish Reconquista destroyed the remaining Muslim enclave in the Iberian Peninsula in the late fifteenth century, Spanish Jewish

(Sephardic) populations had been allowed to convert to Christianity to avoid persecution by royal and Catholic Church authorities, which a significant number of Jews eventually did. With the fall of Granada in 1492, the official expulsion of the remainder of Spain's unconverted Jews was enacted by royal decree at the behest of Ferdinand of Aragon. However, given that a large number of Jews had already converted to Christianity (known as conversos), the actual numbers of expellees is not as sizable as past historians had assumed. Nonetheless, Spanish royal and Inquisition authorities had found it necessary to remove Jews from Spain to ensure the "purity" of the realm from the corrupting influence of Jews (particularly the converso population) and thereby guarantee the ecclesiastical uniformity of the Catholic realms. Moreover, widespread accusations against conversos clandestinely practicing Judaism (Crypto-Jews known as Marranos) also prompted investigations by Spanish Inquisition authorities, which often turned Jews and conversos against each other. As a result of these episodes, many Spanish Jews migrated to Portugal, Italy, and the Ottoman empire, which while relatively more tolerant to Jews than Spain were not free of anti-Semitic prejudices of their own. Portugal expelled its own Jews in 1498 due to a scheme by King Manuel I to marry Isabel, daughter of Fernando and Isabel. However, fewer Jews actually left Portugal than Spain, as many were forcibly converted to Christianity in the year leading up to the expulsion because the king recognized their value to the economy.

The Protestant Reformation of the sixteenth century and the Wars of Religion of the seventeenth century also contributed to further Jewish expulsions that scattered their communities mostly within Europe. The Portuguese expulsion of Jewish communities led to an influx of Portuguese Jews into the Netherlands and the Ottoman empire. Many of these Portuguese Jews contributed heavily to the development of Dutch mercantile and financial industries amid the Netherlands' growing conflict with Habsburg Spain in the sixteenth century. Those who immigrated to the Ottoman realms also contributed to the financial and cultural wealth of their new host country. Moreover, many Portuguese Jews also migrated into German cities, primarily

in the Protestant states of the Holy Roman Empire. However, with the vitriolic anti-Semitic rhetoric espoused by Martin Luther, Lutheran cities expelled their existing Jewish populations, many of which moved to the Catholic south under the protection of Habsburg Charles V. Despite his Catholicism, Charles V protected Jewish communities in his German realms, as they contributed to his fiscal needs in the form of loans. Habsburg protection of Jewish communities continued well through the Thirty Years' War, in which Jewish communities contributed heavily to the Habsburg cause. However, Jews in other Habsburg realms, such as in Italy, were still expelled. In some cases, other regions that had expelled Jews in prior centuries became more amenable to allowing their return, such as England and, to a lesser extent, France. Under Oliver Cromwell's Protectorate, Jews were allowed to enter England in 1656, primarily wealthy Jews from the Netherlands. French expulsion of Jews continued unabated in the southern regions, forcing many to migrate north or into German cities. French Jewish communities in Alsace, who were crucial to Bourbon finances, were protected from expulsion. While anti-Semitism remained prevalent and outbreaks of violence against Jewish communities continued throughout much of Europe, outright expulsions decreased toward the end of the eighteenth century, with the exception of Russia and its establishment of the Jewish Pale of Settlement in its western regions.

Overland Trade Continues and Increases

In spite of the development of transoceanic trade networks out of Europe to the rest of the world from the fifteenth to sixteenth centuries, much to the benefit of countries such as Portugal, Spain, England, France, and the Netherlands, Eurasian trade networks continued to thrive and expand. While Europeans sought to find the best maritime routes to the sources of spices in Southeast Asia, the old overland trade networks continued unabated and, in fact, were further stimulated by these new entrepôts that developed from the Horn of Africa to the Philippines. The so-called gunpowder empires of Central Eurasia (Ottoman empire, Sassanid Persia, and Mughal India) managed to develop and maintain the older overland trade routes regardless of the expansion of European maritime trade networks. Moreover, these two overarching trade networks became complementary rather than competing in this period of global economic consolidation. However, this development led to the long-term decline of Eurasian predominance

in the global economy as European hegemony gradually exerted its influence on regional commercial and political autonomy.

The overland trade routes that carried the majority of goods from the eastern Mediterranean over the steppes and into the Far East were maintained primarily by the Islamic gunpowder empires during much of this period. The Islamic empires ruled over territories that had been pivotal to transcontinental trade in prior centuries. As such, these maintained their position and figured prominently as crucial links in the development of a global commercial network. Regardless of endemic warfare between the Ottoman empire and Sassanid Persia, trade between these two realms was crucial to their economic stability and thus that of the entire region. While initially resistant to European (primarily Portuguese and Dutch) encroachments on their territorial peripheries, the gunpowder empires gradually grew amenable to trade with the West as international trade became a viable means to ensure economic stability and diplomatic maneuvering against other European powers.

The growing prominence of European trade in the economies of the gunpowder empires became evident in the form of trading stations on their peripheries, which further stimulated internal trade within these realms. The Ottoman city of Bursa was the main entrepôt of silk from Persia to be sold to Italian traders, in essence a link between the Mediterranean and Central Asia. Diplomacy also figured into the gradual extension of trade privileges to Europeans. Special trading concessions were granted to England and France by the Ottomans in exchange for support against Spain. The Ottoman city of Aleppo served as a major hub for overland trade and European subsidiaries of joint stock companies, such as the English Levant Company. The Safavids also extended commercial privileges to Europeans, creating Isfahan as a major hub for transnational trade. European merchants purchased Safavid silk, ceramics, and crafts, among other regional goods. The Safavids granted concessions to the English East India Company, the French East India Company, and the Dutch VOC (Vereenigde Oost-Indische Compagnie, or Dutch East India Company). Goods from Eurasia flowed down to these European outposts, further

► HINDU MERCHANTS OF MULTAN

The Indian city of Multan served as an important hub for international trade for the Mughal empire in the seventeenth and eighteenth centuries. Its mostly Hindu merchants were spread far and wide in the expansive search for new markets and sources of goods by the Mughals. Multan was at the crossroads of both the sea and overland routes that connected India with Iran, Afghanistan, and the Arabian Sea. As a result, a Multani trade diaspora developed along Central Asia, Sassanid Persia, and southern Russia, becoming an integral component of the overland trade routes and their expansion in Eurasian commerce. These Multani merchants traded goods from Central Asia to English merchants along the Mughal concessions. Many Multani merchants and bankers settled in places like Bukhara and Samarkand. Furthermore, they had established their own trading stations and settlements in Russia, Afghanistan, and Persia, akin to those of the Europeans in India.

—Abraham O. Mendoza

stimulating internal Eurasian trade along the old overland routes as merchants sought to sell their goods to the international market. Military goods and assistance were provided by the English in exchange for further economic concessions. The Mughals also granted concessions to European merchants despite their already thriving domestic economy. Due to the tremendous influx of income derived from foreign trade, the Mughals encouraged the development of trading stations by Portuguese, Dutch, English, and French merchants. Moreover, Indian merchants also created their own trading companies to further internal Eurasian trade, ranging from as far as Russia to Indonesia. This further cemented the reliance of the overland trade networks on the expansive European transoceanic routes.

In spite of these developments, the Islamic gunpowder empires gradually became dependent on European goods and investment for their economic well-being. Growing European influence and internal problems led to the gradual loss of power on the part of these empires. While the Ottomans and the Safavids were able to keep the Europeans at arm's length for a few more centuries, the Mughals became increasingly vulnerable to growing English power in South Asia. The Mughals were only able to maintain regional power by assuring the English East India Company of their compliance with their commercial demands. In due time, they would succumb to English military and then political control. The Ottomans and Safavids, despite their nominal political independence, were reliant on European trade for many of their goods. By the eighteenth century, these Islamic realms had gradually evolved to mere peripheries to the Europe-centered world economy, with the overland trade routes evolving into another crucial component to the transcontinental and greater transoceanic trade network developed by the Europeans.

The East Indiamen Ships and Their Voyages to and from India

One of the most enduring images of the East India trade is the Indiamen, the huge wooden sailing ships employed to bring Asian goods to European markets during the early modern age. However, very little has been written about these vessels despite their important role in linking the premodern world's economies. Indiamen evolved, over three centuries, into the specialized vessels of the late eighteenth and early nineteenth centuries. Yet there was never one type of ship called an Indiaman. The name referred to the ship's function as an Indian Ocean trader, not to its construction.

The Portuguese, who dominated long-distance maritime trade between Europe and Asia throughout the sixteenth century, originally used caravels. The ships that sailed under Vasco da Gama's journey to India in 1497 averaged only 150 tons, a ton being a measure of cargo volume rather than weight, each ton the equivalent of a large Burgundy wine cask. However, the average size of the ships increased dramatically, first to around 300 tons and finally to around 400 tons during the period 1511–1520. Even as these ships increased in weight, many ships were wrecked due to the poor navigational technology and the fact that the Portuguese mariners were braving seas more or less unknown to Europeans. Additional ships were destroyed in battle, and others were taken by pirates during the sixteenth century.

The Portuguese realized that at least two fleets were needed for the East India trade: a "Europe" fleet to carry cargo to Lisbon from a few assembly points in Asia, its departure timed to coincide with favorable monsoon winds, and a fleet of interregional traders, operating year-round, to supply the assembly points. These latter ships, far more numerous and often much smaller than the ships of the "Europe" fleet, were later on called "Country" traders and were owned and operated by Indian or private European merchants. The Dutch, English, French, Danes, and Swedes all entered the East India trade during the late sixteenth century and the seventeenth century, and they all developed Indian shipyards, if possible, and adopted a two-fleet system. Meanwhile,

➤ MANNING THE EAST INDIA FLEETS

Sustaining the large crews of Indiamen was extremely difficult, especially during the seventeenth and early eighteenth centuries when so little was known about diseases such as scurvy and the fevers that struck down European mariners on long voyages and killed them by the dozens in the tropics. In order to entice European sailors to join the East India fleets, despite notoriously high casualty rates, seamen were offered high pay (if they survived) and a small amount of cargo space for their own trade goods. The same incentives, on rather more generous terms, inspired the ship's officers. Ship owners were not especially choosy either, and men were hired regardless of nationality. Dutch and Italian sailors often were thus found on English vessels, while Dutch ships sailed with Englishmen, Danes, and Germans on their rosters. Even so, as men died along the way, all Indiamen took on sailors wherever they could find them. The Azores and Madeira provided many Portuguese mariners for English and Dutch vessels, and all ships signed on Indian, Malay, and Chinese seamen by the score during the course of a two- or three-year voyage across the Indian Ocean and back. Indian sailors, called Lascars, were a permanent presence aboard East India Company ships, serving under *syrangs* ("captains"), who acted as bo'sun's mates. After the 1750s, improve-

The Return to Amsterdam of the Fleet of the Dutch East India Company in 1599, by Andries van Eertvelt, early seventeenth century. (The Gallery Collection/Corbis)

ments in ship architecture made vessels healthier by increasing ventilation below decks and making rigging and sails somewhat easier to manage. The East India traders also learned how to manage their sailors' diets better in order to preserve their health. Thus, by the end of the eighteenth century most Indiamen sailed with a compliment of about 100 men, but the multicultural composition of the crews did not change.

—James Hoover Frey

demand for Asian goods increased, and "Europe" ships grew in size to accommodate the expansion of trade, becoming slow, vulnerable, and the richest prizes afloat, hunted by pirates, commercial rivals, and enemy navies alike.

During the seventeenth century, the East India trade was a military-commercial venture, with systematic naval campaigns paving the way for the hostile takeover of sources of production, markets, and sea routes. Blockades and regular patrols were maintained to stifle rivals or cajole Asian sailors into buying passes or trading at particular ports. East Indiamen changed to reflect this aggressive mood, becoming sturdier vessels designed to carry up to 36 cannon. The early fleets of the Dutch Vereenigde Oost-Indische Compagnie (VOC) were essentially flotillas of warships combining piracy and raiding

with trade. Ships sailing on the "Cape route" to Europe, however, had to be both heavily armed and large enough to carry their share of the annual Amsterdam-bound cargo. For the most part everyone else copied Dutch methods and ship designs, because the Netherlands was viewed as an advanced maritime power throughout the seventeenth century.

During the eighteenth century Indiamen changed yet again, this time in response to the pressure of competition as the number of European vessels sailing to Asia increased to keep pace with rapidly expanding Asian economies and the ever-increasing demand for Asian commodities in Europe. By this time, most "Europe" ships ranged in size from 500 tons to about 800 tons. Their impressive size and weight required an enormous expanse of sails—as much

as 13,000 square feet or 1,208 square meters—suspended from masts that had to be large and sturdy enough to hold up such a mass of canvass. Large skilled crews were needed, since every maneuver and change of wind required men to climb aloft, sometimes over 90 feet (27 meters) above the decks, to take in, let out, and adjust the sails. Still, the ships were slow and, sailing at five to seven knots an hour, were slower than most warships of the time.

As royally licensed monopolies, all East India companies owned a core fleet of their own ships but hired other vessels, usually owned by groups of merchants, to sail to the Indian Ocean and carry their trade goods. One of the perquisites they offered to private carriers was a chance to engage in “private trade” in certain goods within the East Indian monopoly zone. In 1708 the British East India Company absorbed the older Company of London Merchants Trading to the East Indies and thus controlled a fleet of 5 “Company” ships and 46 hired vessels. During most of the eighteenth century in fact, approximately 150 European ships were involved in the East India trade. By the middle of the eighteenth century many Asian kingdoms also were building European-style ships of their own, and the Indian state of Mysore, under Tipu Sultan, even set up its own trading company, with a small fleet of ships based at Mangalore. Ships built by Asian yards often were just as large as European vessels and sometimes bigger. The wreck of a massive merchantman of Asian origin has been discovered in the Red Sea off the coast of Egypt, heavily laden with goods from the East Indies.

Like the Dutch, the British and French soon developed shipyards specializing in the construction of Indiamen. In Britain in order to protect these yards, laws were enacted preventing Indian-built ships from sailing to Europe. Consequently there was a trend toward the standardization of Indiamen, their equipment, and their operating procedures. Most captains of British Indiamen, for instance, carried printed instructions, about 35 pages long, called a charter-party, with ship’s officers held liable for damage both to the ship and its cargo as well as for the cost of unnecessary halts at foreign ports.

After the 1750s as the British and French began to acquire territorial possessions in India to

match the Dutch empire in Southeast Asia, Indiamen had to adapt yet again to accommodate the needs of a growing number of passengers. Crews’ quarters were sacrificed in order to make room for parties of soldiers and compartments and cabins installed for “the quality” (officials, military officers, and often their wives and children). Aristocratic and wealthy passengers, accustomed only to the best, enjoyed fairly spacious roundhouse cabins in the highly ornamented stern of the ship, with large windows and many homely comforts, such as sofas, musical instruments, and mirrors. However, most of the passengers were young men, often teenagers, who signed on to work for the East India Company as junior army officers or clerks, or “writers,” and they slept in hammocks in the main deck steerage compartment, their fare paid for by the company at a fixed rate.

During the 1780s the size of Indiamen increased again, this time to keep pace with imperial expansion as the British conquest of India accelerated. The East India Company’s yards began to turn out a new class of multipurpose vessels of 1,200 to 1,300 tons, designed to serve as warships, cargo carriers, troopships, and luxury yachts all in one. Two or three “India” fleets, consisting of an average of 15 to 20 ships each, sailed from Britain every year, carrying at least 3,000 troops and some 500–600 other passengers in addition to their crews.

At the end of the eighteenth century the range of people aboard an Indiaman included not only company officials but also other Europeans bound for Asia to seek their fortunes: naturalists, painters, scientists, hairdressers, tailors, and even middle-class women angling for rich husbands. The ship was a floating microcosm of Georgian society; everyone was ranked according to a rigid hierarchy, with only the most exalted dining with the captain. Everyone else dined with the lower-ranking mates, sitting at hanging tables suspended in the main deck steerage compartment. Captains did their best to maintain decorum aboard their vessels, but with so many young passengers high spirits often prevailed, and no voyage was complete without at least a few romances developing between young men and women, although the latter were supposed to be closely chaperoned.

Shipwreck, war, day-to-day hardship, difficult work, and the dangers of disease and uncharted waters remained part of the Indiamen's milieu until their heyday suddenly ended in the 1830s with the termination of the East India Company's monopoly and the appearance of steamships in Asian waters. But the inspiration that created the Indiamen and kept them sailing was never eclipsed. The forward momentum of the East India trade was maintained by the unending lure of exotic faraway lands, picturesque scenes, adventure, strange new discoveries, empire building, and most of all the opportunity to make prodigious profits transporting a wide range of high-status luxuries and valuable commodities, ranging from bone china and tea to opium, printed cottons, and saltpeter.

Russian Expansion and Indigenous Population Decline

Beginning in the 1530s, the Russian tsars embarked on a massive program of expansion into eastern Europe and across Asia. By the late seventeenth century the Russian empire stretched from Finland and Ukraine in the west to the Bering Sea and the Sea of Okhotsk in the east and from the Arctic Ocean in the north to China in the south. The reasons for this expansion are

manifold: population pressures, enticements for Russian settlers to migrate, the exploration for and exploitation of natural resources, geopolitical strategy, and military glory. The regions that Russia incorporated were not empty wastelands but rather the homelands of numerous indigenous peoples with their own cultures and ways of life. When and where Russians and indigenous peoples met, changes to traditional indigenous life were bound to occur. Often, these changes were marked by the decline of indigenous populations in the interests of Russian imperial power.

The decline of indigenous populations took various forms. As historian Andreas Kappeler notes in *The Russian Empire: A Multi-Ethnic History*, Russia's imperial expansion was flexible in its approach. The Russian tsars used a range of strategies, which included conventional diplomacy, the creation of protectorates that the tsars later annexed completely, purchasing smaller territories, and the overt use of military suppression, among other tactics. The nature of indigenous population decline often corresponded to the particular form of expansion used by Russia in a specific case. For example, many Yakuts were assimilated, forced to flee Russian territory, or simply killed as Russian forces conquered their territory. Other populations, such as certain Finnish- and Turkic-speaking peoples, were simply absorbed into Russia's dominant culture. As Russian settlers gradually expropriated their lands, Russian Orthodox missionaries converted them to Christianity, and Russian traders forced them to learn Russian to survive economically.

Frequently, the decline of indigenous populations in the expanding Russian empire was simply due to competition for scarce resources. Much of central Asia was already partly depopulated as a result of Mongol conquests from the thirteenth to the sixteenth centuries and the impact of the Black Death from the fourteenth to the seventeenth centuries. Indigenous peoples throughout much of Siberia and other parts of what would become the Russian empire subsisted on hunting, fishing, and herding, as agriculture was limited due to the frequently harsh weather conditions. To survive on the relatively scarce natural resources, indigenous populations

THE YAKUT REBELLION

One example of Russian expansion's high cost to indigenous peoples is seen in the events surrounding the series of Yakut revolts occurring between 1634 and 1642. During this period the Yakut were a Turkic-speaking and often migratory people who subsisted on domesticated cattle, wild game, and fish in Yakutia (now a region of northern Russia). In the early seventeenth century ethnic Russian settlers moved to the region, prompting Russia to annex Yakutia, harshly tax the Yakuts, and exploit the natural resources of the region (particularly furs).

The Yakuts, heavily burdened by the taxes and alarmed at the construction of Russian forts in the region, began a series of rebellions in 1634. These revolts took the form of attacks on isolated Russian settlements and several (unsuccessful)

attempts to capture and destroy the forts. The biggest revolt broke out in 1641 when Russia's attempt to conduct a census of the population and a count of the Yakuts' cattle for the purpose of increasing taxes incited several Yakut clans to go on a killing spree and besiege Yakutsk, the regional capital. However, interclan bickering and vicious punitive raids by Cossack cavalry on Yakut villages soon ended the revolts for good.

Over the next three centuries, the Yakuts and their culture were gradually either assimilated or marginalized. They were converted to Eastern Orthodox Christianity, and many Yakuts were forced out of Yakutia after gold was discovered in the region.

—Matthew DeFraga

tended to be nomadic. However, as Russian settlers moved into an area, they appropriated as much land as they could to eke out an existence, competing for other resources, such as furs, with the indigenous population and severely limiting the area available for indigenous nomadic subsistence. The more numerous Russians, backed by the military might of the Russian state, invariably won this competition, forcing the indigenous inhabitants to flee, assimilate, or face starvation. As a result, the Russian empire became increasingly "Russian" in both culture and ethnicity despite its incorporation of more and more previously diverse lands. Though many ethnic minorities did not completely die out in the face of Russian imperial expansion, their numbers dwindled, and their survival was increasingly dependent on the will of the Russian state.

Safavid Shia as Isolationist Force in Central Asia (Shia as the Majority in the Empire)

A generalization that occurred early on in the study of world history is that after the Portuguese established themselves in the Indian Ocean and other Europeans followed, the great caravan cities of the Silk Roads became irrelevant. As a result, central Asia became stagnated and isolated. This, however, is not quite the case. Indeed, the markets of Samarqand, Bukhara, and other cities continued to thrive. Indeed, the east-west trade still flourished, and the north-south trade may have increased as Russians coveted the markets and territories of central Asia and Indian merchants prospered. Indeed, the only significant change in trade may have simply been the types of goods as European manufactured goods entered central Asia. In this sense central Asia was no longer a thriving hub of luxury goods. Yet central Asia did become isolated in another sense as it became isolated from the larger Islamic world. The reason can be traced to the rise of a militant Shia state in the Safavid empire.

The Safavids traced their origins back to a Sufi named Safi al-Din (1252-1334) whose order, the Safaviya, enjoyed the patronage of the Mongol khans of the ilkhate (1260-1335). Based around

➤ INDIAN MERCHANTS IN CENTRAL ASIA

Indian merchants played a crucial role in the commercial activities of central Asia. While the arrival of the Portuguese and the opening of new trade routes have often been interpreted as the death knell for the caravan trade of central Asia, this is not quite accurate. Indian merchants from the Mughal empire and later serving various European companies continued to ply the caravan routes of central Asia long after the arrival of the Portuguese at Goa.

Indeed, Indian merchants not only traded in the Uzbek khanates but also traded into Xinjiang before and after the Qing conquest in 1757. Among the goods that traversed central Asia were shawls from Kashmir but also cotton, particularly as Russian demand began to exceed the production in central Asia. The economic growth in the eighteenth century appeared not only in the number of goods but also in the migration of Indian merchants to the Ferghana Valley and beyond. Indeed, the Indian merchants became a diaspora in ways similar to Armenian merchants in Europe and the Ottoman empire. Their involvement was more than simple commerce, as they assisted in building and maintaining the trade infrastructure by financing the digging of wells, the repairing of roads, and the building of caravanserais. Furthermore, as most of the Indian merchants were Hindus, they became a neutral party that fostered trade between central Asia and Iran even during periods of war.

—*Timothy May*

Ardabil, the Safaviya order endured the turbulent period following the collapse of the ilkhate in 1335; the invasion of Emir Timur (1336–1405), also known as Tamerlane; and the rule of the Kara Qoyunlu and Aq Qoyunlu Turkic confederations (Black and White Sheep, respectively).

In the meantime, the Safaviya Sufis proselytized and remained an active influence in the region. In 1447 the order gravitated toward a more militant and millenarian interpretation of their faith that incorporated messianism. In this they expected the return of the Mahdi, a messiah figure in Islam, usually associated with the Imam, or heir of Ali, who could rightly interpret the religion. The leader of the Safaviya gradually was viewed as an emissary of God, chosen to lead

them. During this time the Safaviya alternately allied and fought the Aq Qoyunlu, and the Safavid warriors became known as *kizilbash* (Red-heads) due to the distinctive red hats they wore. In 1488, however, the Aq Qoyunlu crushed them, killed their leader Haydar, and imprisoned his sons, leaving the *kizilbash* and the Safaviya order leaderless.

In 1499 Ismail, the youngest son of Haydar, escaped his imprisonment in Gilan, south of the Caspian Sea. He returned to Ardabil and became the leader of the Safaviya and their *kizilbash* supporters. He quickly avenged his father and expanded Safavid power by taking the important commercial hub of Tabriz in 1501. There he proclaimed himself shah (king). All of this he accomplished before his fifteenth birthday.

He then proceeded to conquer Iran, a portion of Iraq, and Afghanistan. It is during this time that Ismail's leadership and the Safavid Sufi order transformed into a particularly militant form of Twelver Shia Islam. As part of the process in making Twelver Shia the state religion, Ismail required everyone to curse the names of the first three caliphs, thus implying that 'Ali, Muhammad's cousin, was the only legitimate caliph. While considerable resistance to conversion existed prior to the Safavids, Iran was predominantly Sunni. Ismail, however, was not above using force, which persuaded many if only to be spared from further devastation. Ismail also needed the talent of Iranian administrators for his newly won empire. The Iranian bureaucrats, while not usually Shia, converted, but their influence and also the repulsion of the more militant aspects of the *kizilbash*'s religious practices helped mitigate some aspects. Nonetheless, Twelver Shia spread slowly through Iran, despite the ardor of Ismail. Much of it had to do with the dichotomy of the *kizilbash* form, which easily accepted Ismail as the Hidden Imam and also accepted that he knew the will of God. Meanwhile, the *ulema*, or urban religious notables, quietly ignored many of these aspects and generally considered Ismail and his successors as rulers but not necessarily knowing the will of God. At the same time they tended not to voice their disagreement too loudly. Still, by the eighteenth century Iran could be considered a Shia state.

The process of adopting Twelver Shia was more than simply out of faith. It also provided a political ideology that set the Safavids apart from their neighbors, the largely Sunni Ottoman empire and the Uzbeks. By establishing Twelver Shia as the state religion, Ismail attracted the attention of Shia scholars throughout the Islamic world who had long been minorities in their respective realms and were often persecuted. Furthermore, the meteoric rise of Ismail and his liberal practice of distributing plunder also attracted the support of Turkic pastoral nomads throughout the Middle East who often chafed at the increasing centralization of the state and power by the Ottomans, the Mamluk sultanate, and even the Uzbeks, which limited their movements and also placed standardized taxes and services on the nomads. Twelver Shia also allowed the Safavids to cast their wars against their neighbors as holy wars against heretical Muslims. This also assisted in galvanizing the mind-set of the empire's population.

From the onset of their rule the Safavids tended to be the antithesis of the Ottoman state, and this ultimately resulted in a confrontation. The Safavids had already disrupted an Ottoman attempt to invade the Safavids on two fronts as Ismail defeated Muhammad Shaybani, the Uzbek khan, at Merv in 1510. The major battle occurred at Chaldiran, near Lake Van, in 1514. Selim "the Grim" I's use of artillery devastated the kizilbash nomadic cavalry. Only the janissaries' refusal to march against Tabriz spared the Safavids from further humiliation. As Ismail had claimed to be the Hidden Imam, he was not supposed to lose battles. War continued periodically between the two states until the fall of the Safavids in 1736, but the emergence of the Safavids tremendously altered the Middle East and central Asia.

Because of the rise of an empire based on a religious ideology that was diametrically opposed to that of its neighbors, a regional rift occurred. Combined with the fact that the Safavids also courted the nomads of the region, a substantial military force for all of the empires, the Ottomans and Uzbeks looked at the Safavids with suspicion. Pilgrims from Iran to holy sites in Arabia or Iraq could easily be proselytizing missionaries or spies. Furthermore, although the Safavids' origins were based in Sufism, they began

to persecute Sufi orders in the seventeenth century, which also helped the Shia ulema to embrace the Safavids. In the minds of the Safavids, the Sufis undermined the authority of the Hidden Imam. Other religious minorities also faced persecution, a quite different situation from traditional Islamic empires. In effect, as the Safavid empire transformed into an almost exclusively Shia state, it also became a buffer between the Sunni Middle East and central Asia.

Although trade with the Ottoman empire and the Uzbeks did continue, the constant warfare on the borders disrupted the caravan trade and all other forms of travel. Hence, commerce became more regional. This also affected education and the spread of ideas. Whereas scholars might travel from Timbuktu to Samarqand or Bukhara to Cairo, the existence of the Safavid empire halted this transfer of knowledge. Sunni scholars risked death to pass through the Safavid territories. The Ottomans remained very much the center of Dar al-Islam by virtue of not only its military strength and vast empire but also its control of the Holy Cities of Mecca and Medina as well as the al-Azhar University. Thus, the Ottoman empire attracted scholars from throughout the Muslim world. But reaching central Asia was much more difficult. Two other routes existed to reach central Asia. The northern route through the Pontic and Caspian steppes was fraught with peril. Indeed, the safest route was from India and through Afghanistan.

As a result, the Islam of the Uzbek khanates and scientific development stagnated without the infusion of new ideas and the debate that surrounded it. Even militarily central Asia's growth was stunted. The Safavids did their best to prevent improved artillery from falling in the hands of the Uzbeks. To be sure, the Uzbeks did receive new knowledge in all fields but usually much later than other regions. What is most important is that the direction of the contact changed. Although central Asia was still part of Dar al-Islam, it increasingly had contact with Russians who desired central Asian cotton and other goods or with Mughal India but primarily through Hindu merchants. Thus, while commercial goods continued to flow, the intellectual world of central Asia became more limited. Scholars and others purchased books, but these were still produced

by copyists rather than printing presses, so their circulation remained limited. Then combined with the fragmentation of the Uzbek khanate, partially due to the wars with the Safavids that devastated the frontiers agriculturally and economically and the expansion of Russia, the resulting political and military instability further isolated central Asia from a larger involvement in the wider Islamic world.

From the Manor to the City—Continued Urbanization in Europe

Europe underwent a period of rapid urbanization beginning in the fourteenth century and lasting well into the twentieth century. Though cities existed throughout the Middle Ages as centers of trade and defense, they were, by modern standards, relatively small. The mass migration of agricultural workers from the countryside to the city from the fourteenth to the eighteenth centuries provided an ample workforce for Europe's Industrial Revolution that followed. Pull factors, such as employment opportunities and the desire for personal and familial betterment, and push factors, such as the enclosure movement, both contributed to the mass migration of European peasants and the corresponding urbanization of Europe.

Broadly speaking, the medieval manor was a settlement ruled over by a lord and populated primarily with free peasants and serfs, who

worked strips of land overseen by the lord in exchange for protection and a portion of the goods produced from that land. Often, these workers would have their own plots of land as well and had access to communal grazing land for livestock, such as sheep. This system is often termed "open field," as the lands were, in a sense, communal, and peasants jointly worked the land strips. Though manorial systems widely varied throughout Europe, peasants were usually required to work on their lord's land for a certain number of days per month, and serfs, though holding various rights, had to ask permission to leave the land and to do certain other things, such as marry.

Though payments to the lord were initially made in kind (meaning a portion of the goods produced or of livestock or other manufactured items, such as cloth), the rise of the monetary system throughout Europe meant that late medieval peasants often paid their taxes in coin, which they obtained through the sale of their produce at markets in nearby towns. As agriculture became more efficient fewer peasants were needed to work in the fields, which freed up more time for commoners to earn money through the sale of excess produce or through the home manufacture of goods that they could sell at market. This increased revenue meant increased savings, and agricultural workers became intertwined in the trade centered on Europe's growing cities. In addition, the Black Death, which hit Europe in the mid-fourteenth century and continued to strike well into the seventeenth century, drastically reduced the number of peasants available to work on the manors.

Though obviously traumatic in the short term, in the long term the workforce shortage caused by the Black Death meant that the demand for peasant labor grew, and correspondingly so did the wages paid to workers. To lure peasants to their lands, lords granted greater rights to peasants. The increasing freedom and income enabled enterprising peasants to significantly improve their family's situation, allowing family members time for education and prompting them to move into other trades, often in the cities.

By the fifteenth and sixteenth centuries the open-field system was beginning to die out, mainly because the raising of livestock became

THE ENCLOSURE MOVEMENT

Involving both legal and physical changes over the course of several centuries, the enclosure movement wrought fundamental changes in both land use and agricultural practice for much of rural England, with particularly serious consequences for peasant society. In practical terms, the enclosure movement was the process in which a modern system of private land management replaced medieval traditions of communal land use. In 1700 half of the arable land in England was held and farmed according to traditional practices guaranteed by local custom rather than by law. Between 1750 and 1800 about half a million acres (over 200,000 hectares) of land were enclosed by successive parliamentary enactments, culminating in the General Enclosure Act of 1801. Although methods differed regionally and over time, the enclosure movement proceeded rapidly from 1450 to 1750 and was largely complete by 1850.

Some historians have argued that rates of enclosure were closely linked to rising grain prices after 1750, which spurred landowners to enclose their lands and cultivate them more effectively in

order to maximize profits. However, enclosure threatened the existence of traditional peasant society and undercut the paternal relationship that had connected landowner and tenant since the Middle Ages. Because use of common lands by peasants was central to their survival, enclosure led to widespread resistance in the countryside. Opposition to enclosure focused largely upon the perceived injustice associated with the process. The conversion of common lands to private management has often been considered a critical stage in the emergence of agrarian capitalism.

increasingly profitable. As livestock needed to be contained, many open fields were enclosed and made the private property of the manor lords (this long-term trend is called the enclosure movement). Those peasants who were not fortunate enough to move to the cities voluntarily due to a financial windfall were now often forced to vacate their lands to make way for greater pasturage. The only place for these landless and jobless peasants to go was to the growing cities.

By the eighteenth century the beginnings of an industrial economy, fueled by the mass production of goods such as cloth, were seen in western Europe, particularly in England. As the new manufacturing centers for mass production, initially powered by water, were located in towns, agricultural workers flocked to urban areas to find work. The effect of all of these migratory factors was the beginning of a large-scale transformation of western Europe (though not fully realized until the twentieth century) from an agricultural world to one centered on the city.

European Immigration to North America

After the initial period of the voyages of discovery in the fifteenth century, the sixteenth and seventeenth centuries saw a vast influx of European immigrants settling in North America,

particularly along the Atlantic and Pacific peripheries. The colonization of North America along the Atlantic seaboard was characterized by English, Scottish, Scots-Irish, Irish, German (from the various German states of the Holy Roman Empire), French, and, to a lesser extent, Spanish, Dutch, and Swedish settlements from Nova Scotia to Florida and Louisiana. Along the Pacific Northwest, Russian fur traders migrated into Alaska, entering from the Bering Strait into Vancouver and into California. Spanish settlers, mostly soldiers and clergy, also migrated into California to counter both English and Russian excursions in that area and to create a buffer zone for their more valuable colonies in Mesoamerica.

In the early sixteenth century, most of North America was unclaimed by either the Spanish or the Portuguese, who were focused on establishing colonial dominance in Mesoamerica and South America. Early English (Giovanni “John” Cabot in 1497) and French (Jacques Cartier in 1535) efforts to discover a direct Northwest Passage to Asia to circumvent Spanish and Portuguese southerly routes inadvertently resulted in the charting of the vast lands of North America along what is now the eastern seaboard of Canada and the United States. The fisheries of Newfoundland, the fur trade along Hudson’s Bay and the St. Lawrence River, and the plentiful lands along the Chesapeake and Massachusetts Bay would eventually draw hordes of Europeans. Subsequently, English, French, and Dutch ambitions to counter Iberian domination of the New World encouraged state and private investment in colonization of Atlantic North America.

Early attempts at settlement were characterized by hardship, given the lack of familiarity with local resources, climate, and the harsh environment of North America. The earliest English settlement of Roanoke (North Carolina) in 1585 was a complete failure due to the hardships endured by the settlers in the midst of an inhospitable environment and the outbreak of disease. In 1607, the Jamestown settlement (Virginia) was also nearly wiped out for reasons similar to that of Roanoke but was saved due to the assistance of local indigenous Americans. In 1620, religious dissidents from England (Puritans) settled along Massachusetts Bay, establishing colonies along Plymouth. French claims in Canada

included the province of Quebec and Nova Scotia. Dutch excursions under explorer Henry Hudson charted Hudson’s Bay (Canada) and New Netherland (Peter in 1614, later New York, New Jersey, and Connecticut), claiming them as colonies for settlement for the United Provinces (Netherlands). Contemporary New York City was initially founded as New Amsterdam as a Dutch settlement. In 1638, Sweden claimed New Sweden (Delaware and parts of New York and Pennsylvania). These early colonial ventures established bridgeheads for growing numbers of later immigrants from the mother countries.

British North America was settled primarily by immigrants from the British Isles (English, Irish, Scots, Scots-Irish, and Welsh) but also by German, Dutch, and Swedish settlers. British colonial ventures were characterized by their development under the auspices of investment strategies on the part of the English Crown, joint stock companies, and individuals. However, the northern and southern colonies developed along different trajectories given their settlement strategies based on labor recruitment.

British colonies in southern North America, much like those in the British Caribbean, developed as cash crop economies based on plantations, which initially depended on indentured servants from the British Isles. Many Scots-Irish (Scots who initially settled in Ireland as plantation owners) transplanted their plantation agricultural strategies in mid-Atlantic and Chesapeake Bay colonies, utilizing indentured servants from England and Ireland. Indentured servitude was a form of contract labor in which an individual would work for a proprietor of a plantation, during a range of three to seven years, in exchange for transit costs. British convicts were also shipped to North American southern colonies in an effort to rid England and the British Isles of “undesirables,” many of them working under contractual obligations similar to that of indentured servants. The perceived unruliness of indentured servants led to their gradual replacement by African slaves from the Caribbean and West Africa following the 1676 rebellion in the Virginia colony (Bacon’s Rebellion).

British North America’s northern colonies, such as the Massachusetts Bay Colony, developed as colonial ventures of individual proprietors,

small farmers, and small-scale manufacturers in addition to the development of shipping and maritime trade. While many of these colonies were purportedly established as religious havens, they were essentially under English royal control. Many religious dissidents (Quakers, Baptists, and Puritans) from the British Isles sought refuge in these northern colonies due to Anglican discrimination and limited opportunities back home. (Ironically, once in America, Quakers and Baptists suffered discrimination at the hands of Puritans in Massachusetts Bay.) As subjects of the English Crown (British Crown in 1707), many Scots, Irish, and Welsh immigrants flowed into British North America, as did Germans from various German states. William Penn's colony of Pennsylvania ("Penn's woods") became a magnet for German settlement from various southwestern German states, German-Swiss cantons, Rhenish districts, Alsatia, and Westphalia. In the late seventeenth century, the Dutch and Swedish settlements were consolidated under English authority, becoming destinations for further emigration from the British Isles. Immigration to colonial British North America peaked between 1760 and 1775, with an annual influx of an estimated 15,000 annually. Approximately a quarter million immigrants entered in 1775 (55,000 Protestant Irish, 40,000 Scots, 30,000 English, and 12,000 German speakers), many of them still under indentured servitude (65,000).

French North America, mostly established as a royal colonial venture and limited to French Catholics and fur traders, stretched along vast tracts of Canada from Quebec and Nova Scotia (New France) to Louisiana in the Gulf of Mexico. From 1664 to 1680, French settlements along the St. Lawrence received 2,000 indentured servants, 1,000 settler-soldiers, and 1,000 women (for the purpose of establishing families). Some of these settler-soldiers were initially German and Swiss. Louisiana attracted an estimated 7,000 settlers between 1717 and 1721. Unlike the English colonies, French colonial recruitment was undertaken by large proprietary owners (seigneurs) who were limited to recruiting French Catholics, as Protestants were barred from immigrating to French America. Furthermore, immigration to New France remained low throughout the seventeenth and eighteenth centuries, with the bulk of

THE GERMAN EXPERIENCE IN COLONIAL NORTH AMERICA

Despite the common cultural and linguistic commonalities that existed among the German peoples of central Europe in the seventeenth and eighteenth centuries, the lack of political consolidation and religious differences accounted for the divisions in people's sense of what it meant to be German. The Holy Roman Empire of the German nation, which in the seventeenth and eighteenth centuries was a politically fragmented political entity composed of dozens of principalities, kingdoms, imperial cities, and duchies in addition to ethnic groups that while not nominally German were German speakers (Czechs), further complicated what it meant to be German. Thus, German colonists in North America came as Rheinlanders, Hessians, Westphalians, Brandenburgians, and Prussians but also as Protestants and Catholics. In spite of these differences, Germans immigrated to specific colonies (most notably Pennsylvania) in British North America and were identified as Germans by their hosts.

William Penn's colony of Pennsylvania, which means "Penn's woods," became a haven for German immigrants to British North America. A proprietary colony developed by Penn to serve as a model utopia of settlement, it was heavily populated by Germans due to recruitment efforts geared directly toward them. The heavy German influx into Pennsylvania created a distinct German cultural region (frequently and incorrectly called Pennsylvania Dutch), contrasting with the adjacent English colonies. High rates of German immigration well into the period of the American Revolutionary War led to debates over what the national language of the early republic should be.

—Abraham O. Mendoza

French emigrants going to the French Caribbean. By the mid-eighteenth century, New France's population was an estimated 55,000 and Louisiana's was approximately 4,000, more due to natural birth rates than immigration from France.

From the sixteenth century to the eighteenth century, Spanish settlement in the Atlantic and the Pacific regions of North America was in reaction to Protestant North European emigration in an effort to create buffer colonies

to prevent incursions from the north. The colony of St. Augustine in Florida was established in 1565, and Santa Fe (New Mexico) followed in 1598. Russian and English interest (most notably that of Sir Francis Drake's charting of the California coast in 1579) in California in the eighteenth century led the Spanish to settle their claims in the region. Spanish military expeditions and Catholic missions into New Mexico and California led to the establishment of Spanish authority and settlement in the region. The Spanish military established forts (presidios) in San Francisco, Monterey, and Santa Barbara to spearhead migration from New Spain (Mexico). Ecclesiastical settlements, through the efforts of Franciscan friar Junipero Serra, led to the development of various missions in California, which were institutions geared toward acculturating the local indigenous peoples to Spanish culture. Spanish towns (pueblos), such as San Jose and Los Angeles, were also established as secular settlements of immigrants from New Spain, mostly of mestizo (mixed European and indigenous) descent.

Russian expansion into North America followed their settlement of vast tracts of Siberia and Central Asia in the seventeenth and eighteenth centuries. Russian explorer Ivan Fedorov entered northern Alaska in 1732. In 1741 the Aleutian Islands, southern Alaska, and northwestern North America were discovered during the Russian exploration by Vitus Bering and Aleksei Chirikov. In 1784 Grigory Shelikhov was responsible for establishing the first Russian settlement in Alaska. In 1799 Nicolai Rezanov established the Russian-American Company for hunting otter for the Russian fur trade. The Russian population in its North American settlements was minimal when compared with other European settlements, as these were composed primarily of fur trappers, and most of these were Russified indigenous peoples.

German Immigration to North America

Although Germany has never possessed colonies in North America, Germans have played a prominent role in the exploration, settlement, and subsequent formation of the United States. In 1507 the cartographer Martin Waldseemüller published his *Cosmographiae Introductio* with a world map suggesting, for the first time, the name "America" for the newly discovered continent, in honor of Amerigo Vespucci. Since then, German-speaking peoples have flocked to the Americas to form one of the major ethnic groups in the present-day United States.

German immigrants originated from many territorial states, each with its distinct dialect and culture. They tended to identify themselves by region or religion rather than nationality. This remained the case even after 1871, when Chancellor Otto von Bismarck unified the numerous German kingdoms, duchies, and principalities into one empire. In the United States, such German-speaking "ethnics" as the Saxons, Palatines, Bavarians, Franconians, Hessians, Swabians, and Prussians (to name a few) became "Germans" only to "non-German" ethnic groups, to whom language served as the paramount marker of belonging.

Most German immigrants in the early colonial period were agricultural settlers, peasant farmers, and craftsmen. Some were attorneys, clergymen, or merchants, while others were adventurers, explorers, and fortune hunters. In 1552 Hans Staden from Homberg in Hesse signed on with a Spanish expedition to Brazil, where he was allegedly captured by a cannibalistic tribe. In 1614 Henrik Christiansen from Wesel in Kleve explored the Hudson River. Peter Minuit (Minnewit), also from Wesel, is most remembered for his purchase of Manhattan Island from Native Americans for only 60 Dutch guilders. In the wake of England's Glorious Revolution (1688) that led to the deposition of King James II, Jakob Leisler from Frankfurt, one of New Netherland's (present-day New York state)

wealthiest merchants, led a revolt and took over the government of the colony. Nikolaus de Meyer from Hamburg—owner of a brewery, a mill, and vast tracts of land—became mayor of New York in 1676. Johann Lederer, also from Hamburg, explored west of Virginia. Augustin Hermann, born in Prague, surveyed Virginia, New Amsterdam, and Maryland. From John Smith we learn that some Germans had been among the settlers of Jamestown.

German group migration, however, did not begin until 1683, when 13 Mennonite and Quaker families from Krefeld arrived in Philadelphia aboard the *Concord*, the “Mayflower of German immigration.” Led by Francis Daniel Pastorius (1651–1720), a Franconian, they purchased 15,000 acres (6,070 hectares) of land from William Penn and founded Germantown, the first permanent settlement of German immigrants. Germantown did not remain the only religious German settlement. Germans were, for instance, among the hundreds of Labadists (followers of the French mystic Jean de Labadie), who lived secluded in a monastery founded in Maryland in 1684.

Whereas only a few Germans settled in Puritan New England, many went to New York, Virginia, Maryland, Delaware, and South Carolina. Pennsylvania, however, had always been a focal point for Germans, attracted by the liberalism of its government. Quakers, Mennonites, Dunkards, Schwenckfelders, and Amish were among the German-speaking dissident groups who sought religious freedom there. The Dunkards (Dunkers, Tunkers) came from Westphalia in the 1720s and founded communities in Pennsylvania, Maryland, Virginia, Indiana, Kansas, Ohio, Missouri, and Texas. Conrad Beissel, who had migrated in 1720 and joined the Pennsylvania Dunkards, later founded the Seventh Day Baptists. In 1732 he also founded Ephrata Cloister, a religious community in Lancaster County, Pennsylvania. Ephrata Cloister thrived in the mid-eighteenth century, and two small congregations continued until the late 1970s. The Schwenckfelders (followers of the German theologian Kaspar Schwenckfeld, leader of the Protestant Reformation in Silesia) moved to Montgomery County, Pennsylvania, in 1734. The Moravians (Herrnhuters), who trace their

origin to the *Unitas Fratrum* (Unity of Brethren), inspired by the fifteenth-century Hussite movement (followers of the religious reformer Jan Hus) in Bohemia and Moravia, came to North America as missionaries.

Most German immigrants, however, were Lutherans, Calvinists, or Catholics. Often wavering in their beliefs, they organized themselves in congregations hesitatingly. Heinrich Melchior Mühlenberg, a Lutheran clergyman sent to Pennsylvania in 1742, supervised all Lutheran churches from New York to Maryland and organized the first Lutheran synod in North America in 1748. Michael Schlatter oversaw the German Reformed Church. Both churches have played an important part in the lives of German Americans.

A first mass migration of Germans to North America occurred in 1709–1710, followed by a second wave in 1717. The military campaigns of Louis XIV, the restoration of Catholicism as the official religion in the palatinate, and the stress of harsh winters variously propelled about 13,000 people from the palatinate and upper Rhine region to London. Only a fraction of them, however, arrived in North America. Many went to Ireland, northern England, or Holland, while many others perished.

Until the early nineteenth century, German immigration to North America was facilitated through the “redemptioner” system. Poor Germans received free passage to America in exchange for several years of indentured servitude. An estimated one-half to two-thirds of all white immigrants before 1776 came under this system. Between 1776 and 1782, German princes leased 30,000 German mercenaries to the British Hanoverian ruler to suppress North American rebels. A considerable number of these Hessians (the majority of them came from the principality of Hesse-Cassel) remained in America after the War of Independence and induced friends and relatives to emigrate as well.

German Americans have contributed significantly to American life and culture, including business, politics, philosophy, science, literature, music, and architecture. Among them are such prominent figures as Hannah Arendt, Albert Einstein, Walter Gropius, Henry Kissinger, John Davison Rockefeller, John Augustus Roebling,

Arnold Schönberg, Paul Tillich, and Franz Werfel, to name but a few. Today, more Americans of European descent trace their origin back to German roots than to any other national origin. In the U.S. census of 2000, nearly 42.8 million listed “German” as their primary ancestry, equaling 15.2 percent of the total population. German-American Day, established by congressional resolution and first proclaimed by President Ronald Reagan in 1987, is celebrated on October 6 each year to honor the accomplishments of German immigrants and their descendants.

The Portuguese Discovery of Australia?

The question of which European nation first discovered Australia has intrigued generations of historians. Claims that the Portuguese discovered the continent in the first half of the sixteenth century, decades before Dutch contact in 1606, are among the most contentious. The debate stems from a series of French maps, apparently of Portuguese origin, that depict a landmass remarkably similar in shape to Australia. Aristotle had argued that an unknown southern landmass must exist in order to balance the large landmass in the Northern Hemisphere. Despite the lack of proof, Europeans accepted his theory as factual. Aristotle appeared to be vindicated in

the twelfth century when Marco Polo described a great southern land to the south of Sumatra, ruled by rich and secretive kings.

Supporters of Portugal’s claim argue that Portuguese traders in Sumatra explored the Australian coastline in the 1520s. No Portuguese maps depict this “discovery,” but proponents argue that it remained a secret to maintain a strategic advantage over European rivals. Historians added weight to the claim by pointing to the wreck of “the Mahogany Ship” in Victoria. Last seen in the nineteenth century and never scientifically verified, proponents claimed that the remnants were a Portuguese vessel charting the southern Australian coastline.

French maps, depicting a large southern landmass termed “Java la Grande,” form the crux of the Portuguese claim. They were produced in the thriving French port of Dieppe in the sixteenth century and purport to show the northern and eastern coastline of a vast continent. The maps were produced after a French visit to Sumatra in 1529, and many of the images, depicting flora and fauna, are accurate. Many regions are based on conjecture, however, and are a consolidation of preexisting maps that depict places that the cartographer had not viewed personally. As place-names on Java la Grande are of Portuguese origin, historians have claimed that the French cartographers must have viewed a Portuguese original.

Skeptics have pointed to serious anomalies in the French maps, particularly a large promontory on the east coast of Java la Grande. The historian W. A. R. Richardson has demonstrated convincingly that the cartographers’ error derived from the consolidation of multiple maps. The northern coast of Java la Grande correctly depicts Java’s north coast, but the eastern seaboard was never charted. Instead, without any scale or orientation to locate the chart, mapmakers unwittingly appended a section of Vietnam’s Mekong Delta. Such a practice of filling in the gaps was not unusual in attempts to provide wealthy patrons with seemingly complete and impressive purchases.

Although the Portuguese claim is, at best, highly disputed, the Dutch claim is far stronger. Dutch explorers accidentally made contact with Australia on a number of occasions, having misjudged the route from Africa to the East Indies.

► THE SPANISH CLAIM?

Dutch and Portuguese explorers reached the Asia-Pacific region from the Indian Ocean, but Spanish explorers sailed west from their territories in South America. Under the command of Pedro Fernandez de Quiros in 1606, Spanish ships landed on what is now the island of Vanuatu. Convinced that he had discovered the fabled great southern landmass, Quiros claimed the land for Spain and for the Catholic religion. Although the men founded a colony, New Jerusalem, the isolated outpost struggled to survive and soon collapsed.

Quiros returned home disappointed, but his second-in-command, Luis Vaez de Torres, remained and resolved to continue and find the vital

route from South America to the Spanish port of Manila in the Philippines. Torres' route took him east to the southern coast of New Guinea, where he became the first European to navigate a route through the straits that now bear his name. In the process he proved that New Guinea was an island and probably sighted the Australian mainland. Despite far-fetched claims that the ship sailed south to explore the new continent, it is almost certain that Torres turned north to reach the Philippines. Thus, Spain's claim to having discovered anything more than the northern tip of Australia was left unpursued.

—Robert Mason

The first planned Dutch expedition to Australia occurred in 1606, when Cape York was charted in an attempt to find gold and a possible route between New Guinea and Australia. With no discernable trade opportunities, Dutch interest proved fleeting and declined sharply from the 1640s. English explorers were the first to sight the eastern seaboard in the late eighteenth century as part of Captain James Cook's Pacific voyage. This period of scientific exploration was marked by more detailed cartography on the part of the French and British sailors who pioneered the exploration of Australia's coastline.

A Great Wave—Chinese Migration to Manchuria, Szechuan (Sichuan), Taiwan, and the Southwest

Migration movements have a long history in China, starting with the spread of agriculture from the Yangtze and Yellow river basins about 7000 BCE. Migrations of Chinese into non-Chinese

areas have been recorded since the times of the Han dynasty (206 BCE–220 CE). Of particular significance was the thrust of Chinese migrants to the peripheries of the Middle Kingdom, to the southern and eastern regions during the late Middle Ages and at the beginning of the new era.

The conquest of China by the Mongols and the establishment of their rule in eastern Asia (under the Yuan dynasty, 1280–1368) left deep traces in the Chinese psyche. The fact that “barbarians” had succeeded in dominating the land of great civilization effected long-lasting repercussions in the ways the Chinese organized their state and society in the periods that followed the decline of Mongol occupation.

The Ming rulers set priorities for an effective military strategy to ward off the barbarians of the north and also furthered the migration of Chinese farmers to areas with non-Chinese populations as a means to strengthen political control on the periphery. Under Ming rule, a system of military garrisons (*wei-so* [“guard post”]) was established in the provinces. The presence of imperial army units spurred the movement of Chinese farmers to more distant areas with non-Chinese populations. Once *wei-so* had been established in non-Chinese areas, local leaders (*t'u-ssu*) were selected as agents to serve the interests of the Chinese administration. The lineages of the hereditary *t'u-ssu* acted as intermediaries between the local non-Chinese people and Chinese immigrants.

➤ CHINESE IMMIGRATION TO THE LAND OF THE MATRIARCHAL NAXI (YUNNAN)

Among the non-Chinese groups with which the Chinese migrants came into contact was one with social structures that deviated markedly from the patriarchal clan system of the Chinese, and these are the Naxi (also called Moso) in the southern province of Yunnan. Anthropologists agree that the historical Naxi society was a true matriarchy. The earliest documentation of matriarchal society among the Naxi are Chinese sources dating to the period between the sixth to ninth centuries. In these sources, the kingdom of Qiang in southern China is described as Nü Guo (“land of women”) where only female rulers were in power who nominated only female ministers for their council. The capital of the southern state was Lijiang, founded at the end of the twelfth century on the southern Silk Roads that connected Yunnan with Tibet.

The Queendom of the South was conquered by the Qing (Manchu dynasty) in 1724 and was ruled since then by vassal kings, loyal to the Manchu emperors. Under the influence of Chinese immigrants to the Naxi land, the matriarchal order (with the mother as head of the household and key figure of kinship relations) dissolved among most of the Naxi. Traces of the historical matriarchy

have been preserved up to the present among regionally isolated communities of circa 8,000 Naxi scattered around the Lugu Lake, about 185 miles (300 kilometers) from Lijiang. The matriarchal Naxi form the Eastern group within the wider Naxi population, which is predominantly patriarchal.

In the heritage of local traditions and folklore, the cultural memory of the matriarchal past has been preserved. A goddess, with the name of Pancisamei, is revered as the patron of Naxi writing, the only system of a purely pictographic script still in use today. Naxi writing is used for religious purposes, for reading and writing sacred texts. Also in architecture, the memory of the once-mighty queendom lives on in key elements of ornamentation. Public historical buildings in China are ornamented with two prominent symbols of Chinese mythology, the phoenix bird (symbolizing the female principle) and the dragon (symbolizing the male principle), with the dragon on top of the phoenix, thus symbolizing male dominance. There is only one exception, and this is the local palace of Lijiang where the phoenix is positioned above the dragon as a symbolic reminder of the once-powerful women rulers in the land of the Naxi.

—Harald Haarmann

When they settled in areas with a non-Chinese population, Chinese farmers and members of the social elite did not rely on segregated patterns or on observances of ethnic boundary markings. The Chinese mingled with the local people and established social relationships to form new lineages. The situation was different in Szechuan. This region had been vastly depopulated during the later period of Mongol occupation due to repeated droughts, poor harvests, and epidemics that decimated a large portion of the indigenous population. To a large extent, the Chinese immigration to Szechuan during the Ming era was equal to a re-peopling of the region.

Where Chinese and non-Chinese people engaged in long-term contacts, the situational pressure exerted by Chinese on the minority languages caused processes of gradual assimilation, eventually resulting in the adoption of Chinese

by speakers of non-Chinese languages. The shift from a local language to Chinese unfolded over a prolonged stage of bilingualism, with the local language as the mother tongue and Chinese as a second language. This status of languages is typical also of modern varieties of bilingualism in China.

The majority of the settlers who migrated from the plains of northern China belong to the ethnic group of the Han Chinese. The Han have the status of an independent nationality in the modern state. Also numerous were the Hakka Chinese, whose destinations in the migration movements were mostly areas in the southeast. Hakka Chinese whose region of origin was Meixian (“Plum County”) in Guangdong settled in areas from Szechuan to Taiwan. The name “Hakka” was given to this Chinese group by the Yue (Cantonese), and means “guest” or “stranger” thus pointing to their foreign origin.

The political elite of the Qing dynasty were Manchu (i.e., of non-Chinese descent). The Manchu are of Tungus ethnic stock, and their language, of Altaic affiliation, is distantly related to Mongolian and Turkic languages. As a means of safeguarding the ethnic and cultural identity of their people, the Manchu rulers favored rigid restrictions in social contact. Marriages between Manchu and Chinese were forbidden. Such demands for ethnic segregation notwithstanding, the migration of Chinese to Manchuria was promoted. The Chinese element was perceived as a factor to increase the agricultural workforce and to enhance handicraft and professional skills in the region. The Chinese immigrants contributed decisively to the urbanization of Manchuria.

In the course of the eighteenth century, the Manchu rulers waged numerous wars with their neighbors. As a consequence of the military

expansion of the Middle Kingdom, Chinese migrants settled in areas far away from the Chinese heartland, namely in Turkestan, Mongolia, and Tibet and as far south as Yunnan and as far east as Taiwan, where the local Formosan tribes were driven to the mountainous region in the southeast of the island.

■ Introduction: Agents of Contact

When we think of the acceleration of travel and contact during the early modern period, we tend to think of improvements in nautical technology and mapping. Nevertheless, people—explorers, adventurers, everyday sailors, and missionaries—forged the foundations of the modern world. Europeans and to a lesser extent Asians were trying to reestablish the trade routes that had bound the Afro-Eurasian landmass during the height of the Mongol empires that had offered safe passage for overland travel from Europe to East Asia. The onslaught of the bubonic plague (the Black Death) beginning in the mid-fourteenth century devastated these routes. Nevertheless, throughout the period stalwart Sufi missionaries still circulated through India, western Asia, Southeast Asia, and sub-Saharan Africa. Christian missionaries continued to proselytize across the region. By the late fifteenth century, far-flung societies were beginning to reconnect across the Afro-Eurasian landmass. An unfortunate combination of disease and abnormally cold winters in the late sixteenth and early seventeenth centuries disrupted

economic systems across the northern reaches, probably nowhere to as great a degree as in Europe. Tales of the wealth of Asia were particularly compelling to Europeans. Although at the end of the fifteenth century the Chinese and Muslims were in a period of increased contact with other societies, Europeans led in the urgent efforts of the sixteenth century to expand their reach over the seas. There were many reasons behind the European expansion; economic recovery was no doubt high on the list, as was the imperative to expand Christendom. The networks forged by Europeans during the sixteenth and seventeenth centuries formed the basis for global empires and led to today's interconnected global economies. During one daring venture aimed at finding a shortcut to India, two new continents—the Americas—along with their peoples and their wealth came into the global network. During the period, the most pervasive agents of contact, colonial settlers, established themselves. Contact was often deadly for indigenous peoples, but the new crops, metals, and other resources contributed to demographic

explosions in many areas. The missionaries, soldiers, merchants, adventurers, and settlers traveling to the New World changed the power structures and trading connections of the globe.

Plano da India

The Portuguese developed the Plano da India (Plan of India) in order to fulfill their ambitions to establish direct links with the spice trade in South Asia after warfare closed trade on the overland Silk Roads of central Asia. While the initial planning of the Plan of India can be mostly attributed to Prince Henry (1394–1460) “the Navigator” (who was incidentally never king of Portugal), the credit of carrying it out can be primarily designated to King João II of Portugal (r. 1481–1495). As king, João II encouraged ambitious Portuguese

maritime commercial projects and plans of expansion in Africa and South Asia, and he made Atlantic exploration his top priority. Ultimately, the Plan of India resulted in the establishment of Portuguese commercial expansion and settlement (Estado da India, or state of India) into South Asia in the early sixteenth century.

Prince Henry was an early proponent and advocate of developing newer naval technologies to further Portugal’s establishment as a formidable economic power to increase his own personal wealth. He financed early Portuguese voyages of exploration into the Atlantic as well as western and southern Africa in the mid-fifteenth century. As both a Mediterranean and Atlantic maritime nation, Portugal’s trade was tied to that of the Islamic sultanates of North Africa. However, after the disruption of direct trade with China and India, the Portuguese sought new methods to expand the Asian spice trade. In addition, Marco Polo’s tales of the exotic East also influenced Henry the Navigator. Yet Portuguese efforts were limited to the settlement of the uninhabited islands of the Azores and Madeira, a failed attempt to conquer the Canary Islands, and incursions and trade settlements in African domains, where they established trade in slaves, gold, and ivory.

It was not until the reign of King João II of Portugal that efforts at establishing commercial links and settlements in India were successful. In 1488, Bartolomeu Dias’ discovery of the African Cape of Good Hope in southern Africa provided a new sea route to the Indian Ocean. The discovery of the passage around Africa was significant because it signaled the potential of direct trade with India, bypassing the overland route (the Silk Roads) through the Near East and Central Asia. By 1498, during the reign of Manuel I, Vasco da Gama successfully sailed around the Cape and then around eastern Africa (Kenya) and finally landed in India. In establishing this direct link with India, Portuguese explorers and merchants began the process of establishing trade settlements and enticing local Muslim rulers to establish trade relations.

The state of India was established in the early sixteenth century under Portuguese authority and was created with the purpose of extending political and legal control of Portuguese colonies

➤ PORTUGAL—CONNECTING EUROPE AND AFRICA

In spite of the widespread use of disparaging remarks and crusader rhetoric made against the Muslim world, many Portuguese explorers, merchants, and elites were able to move freely in North and western Africa in the late fifteenth and early sixteenth centuries. Portugal’s existence as a crusader state was characterized by its struggle against Muslim rule in the Iberian peninsula (completed prior to the *reconquista*). Yet Portugal also established trade relationships with adjacent Muslim sultanates in North Africa and along the western African coast early in its history. Jewish merchant networks in both Portugal and North Africa facilitated this trade for both sides in spite of the religious divide between Christendom and Islam.

As a Mediterranean and western Atlantic European kingdom, Portugal relied on trade with the Muslim world to a greater extent than with the rest of Europe. During Portugal’s age of discovery, Portugal relied on previous trade networks established with Muslims and on familiarity with commerce in the easternmost lands of Islam. In essence, Portugal’s proximity to the Muslim world of North Africa had a considerable influence on its imperial growth in the fifteenth and sixteenth centuries from Africa to the Indian Ocean.

—Abraham O. Mendoza

in India, under the auspices of a European Christian monarch. In a mere century, Portugal managed to extend its commercial and colonial interests in regions of coastal Africa (scattered northern, western, southern, and eastern settlements) and South Asia, eventually including the Spice Islands. During this period, Portugal established various trading ports such as Goa (India), Ormuz (Persia), Malacca (Malaysia), Kochi (India), the Maluku Islands (Indonesia), Macao (China), and Nagasaki (Japan). While protecting its economic network from European, Arab, and Asian would-be competitors, Portugal dominated the trade between Asia and Europe and participated in intraregional commerce within Asia.

Michele Ruggieri—The First Jesuit in China

The Jesuit entrance into China is a story often studied through the person of Matteo Ricci. Ricci's position and role in the Jesuit movement, however, would not have been possible without the work of his predecessor, Michele Ruggieri (Luo Mingjian). Ruggieri and his efforts laid the groundwork for the later Jesuits through his focus on establishing relations with the upper classes in Chinese society.

Michele Ruggieri was born in Spinazzola, Italy, in 1543. Following in the Jesuit tradition, Ruggieri was an accomplished scholar. In Naples, he studied law and eventually earned doctorates in civil and ecclesiastical law. He also studied philosophy at the Collegio Romano. Following his studies, he entered the novitiate at St. Andrea in Rome and left for India in 1577.

In 1579, Michele Ruggieri arrived in Macao after Alessandro Valignano, the visitor to Asian

missions, requested a new missionary. Influenced by Valignano's belief that the Jesuits needed to abandon European civilization and thoroughly adapt themselves to Chinese society, Ruggieri quickly turned to the task of studying Mandarin and written Chinese. Ruggieri's commitment to language study was rewarded in 1580 on his first visit to Canton (modern Guangzhou). As in previous attempts to enter China, Ruggieri sailed to Canton with Portuguese merchants to conduct trade there. His attention to the subtleties of Chinese etiquette and his linguistic ability so impressed the local officials that he was given lodging in a small house normally reserved for tribute missions to the emperor. Ruggieri was also able to win over members of the upper class with European clocks and prisms. Through these efforts, he was able to become friends with the governor of Guangdong and other top active and retired officials. The important work at this time allowed the Jesuit to reside in Canton at various times between 1580 and 1582.

In 1583, Ruggieri was granted permission for himself and Matteo Ricci to permanently reside in Zhaoqing, 60 miles (100 kilometers) upriver from Canton and then the provincial capital, by Wang Pan, the governor of Guangdong. In the tradition of adapting to local customs, Ruggieri decided to adopt the robes of a Buddhist monk and tried to maintain a low profile. Although Ruggieri was able to attain a level of good relations with influential members of the society, others in Zhaoqing were not well disposed to accepting the new position of the missionaries. Rumors of the missionaries' work to erect a large Christian building spread throughout the society. Nevertheless, the missionaries were able to use their connections to Wang and his successor, Zheng Yilin, to retain their position in the city. Ruggieri's work to win over the upper class also allowed him the first opportunity to travel outside the Canton region to Shaoxing, Zhejiang Province, in 1586 with Zheng Yilin.

During his time in China, Ruggieri and Ricci compiled the first Portuguese-Chinese dictionary. In addition to this work and establishing the general traditions of the China mission, Ruggieri also embarked on various attempts at producing religious writings and poetry. However, this was

not only for pleasure; Ruggieri was engaging in the activities of other literati in China. Ruggieri published his first catechism in Chinese, the *Tianzhu Shilu*, in 1584. In addition to writing religious texts, Ruggieri engaged his time reading the Four Books (the Great Learning, the Doctrine of the Mean, the Analects, and the Mencius), elevated by Neo-Confucian scholars during the Song dynasty (960–1279) as the orthodox interpretations of Confucius's writings. Ruggieri also read Chinese poetry and learned the eight-legged essay form that was required for students taking the civil service examinations. In 1585, he published a new compilation of his first catechism in the *Xinbian Xitianzbuguo Tianzhu Shilu*. While his achievements here were remarkable and groundbreaking, many agree that this work was done with the close cooperation of a convert or other local scholar. His catechisms were also negated by the later work of Ricci, which is considered to be of higher quality.

In 1588, Ruggieri left China on a mission to obtain an official papal mission to the Chinese emperor. This was in response to Alonso Sanchez, a Spanish Jesuit, who had circulated the idea of an official Spanish mission to Peking. At one point, Sanchez went so far as to suggest using force to open China to Christianity, a plan

that never came to fruition. Although he never returned to China, Ruggieri left behind the roots of the Jesuit mission in Ricci, who used his predecessor's strategies to cement the position of the China mission and begin the process of spreading Christianity throughout the empire.

■ Introduction: Traditions and Adaptation in Slavery

The development of plantation colonies in the Americas, rise of African slavery, and the establishment and growth of the transatlantic slave trade were the most important trends in the history of slavery between 1450 and 1770. In a separate development, moreover, slavery significantly expanded in the Mediterranean during the first 250 years of this era. Although slave labor was used in all parts of the colonial economies in the Americas, the sugar plantation emerged as the most distinctive feature of New World slavery in the preindustrial period. Plantations are profit-oriented large-scale agricultural estates producing tropical staples for distant markets. Many of the features characterizing plantations were already exhibited by

sugar-producing estates in the medieval Mediterranean, where Europeans had first begun to cultivate the staple. The classic sugar plantation, however, only emerged in the Caribbean in the mid-seventeenth century. These plantations relied almost exclusively on African slave labor and introduced a new and particularly strict work discipline anticipating industrial patterns.

Slaves had not predominated in the workforce of sugar estates in the medieval Mediterranean, nor did unfree Africans constitute the sole source of labor in most early Atlantic and American colonies. Based on economic considerations as well as cultural values, however, American planters eventually came to prefer slaves imported from Africa to other forms of labor.

TRIANGLE TRADE

When the transatlantic slave trade finally ended in 1867, more than 10 million African slaves had been brought to the Americas. But the transatlantic trade is not remarkable just for its sheer scale. It is also set apart by its integration into an intercontinental commerce that linked Europe with Africa and the Americas and led to a degree of rational organization unprecedented in the trafficking of enslaved labor. Finally, the transatlantic slave trade stands out because it has left a particularly visible and significant legacy. The trade created distinctive populations of African descent in the Americas, which have defied the degradations of slavery and not only continue to shape much of the continent but have also made major contributions to today's global culture. At the same time, the

trade is inextricably linked with the rise of modern racism. It is an open question whether the slave trade itself gave rise to racism or whether, conversely, Europeans held racist attitudes toward Africans that only made the trade possible. Once in place, however, the trade and plantation slavery, on the one hand, and racism, on the other, undoubtedly reinforced one another.

Just as Europeans established their first sugar colonies in the Atlantic, another major development in the history of slavery began in the Mediterranean. As long-standing conflicts between Christians and Muslims entered a new phase in the second half of the fifteenth century, the enslavement of captives increased significantly on both sides and made slavery a defining aspect of life in the region. Slaving peaked in the

Mediterranean between 1530 and 1680, but the powers most actively engaged in slaving—the Muslim polities on the Barbary Coast of northern Africa—carried out their last raids as late as the early nineteenth century. Barbary slavers alone may have captured over one million Christian Europeans between 1530 and 1800. Perhaps not all of these captives can indeed be considered slaves, but it is certain that at least through the end of the seventeenth century the term “slave” evoked in Europe the image of a Christian who was rowing a Mediterranean galley to the drum of a Muslim master.

Ten Million Africans— The Demographics of Slavery

One of the most hotly debated questions among scholars of African history and diaspora studies is the exact number of Africans who were captured and sold into slavery in the Americas between the sixteenth and nineteenth centuries. Figures ranging from 10 million to 25 million have been suggested.

Regarding the debate about the number of slaves who were taken from Africa, John D. Fage, a scholar in African history who conducted his research between the 1950s and the 1960s, believed that about 14.65 million Africans were exported throughout the Americas after slavery was officially outlawed in 1833 in the British Empire. Fage believed that there was a mutual agreement between African merchants and

European traders over how to increase the scale of trading. In other words, there was a high demand for both European goods and human labor from Africa. Fage’s conclusion was not received well by many historians and intellectuals, who challenged not only his numbers but also how they were deduced. Notably, Fage’s estimate was challenged by another historian, Phillip D. Curtin, who disputed the numbers, including the mortality rate. Curtin maintains that about 9.566 million Africans were dispersed outside Africa between 1451 and 1870. Curtin’s analysis, which was mainly based on the dispersals of slaves into Europe, North America, and the Caribbean, did not seriously consider the number of slaves who were transported by Portuguese merchants and traders. Also, Curtin’s estimate, which reduced Fage’s estimate by almost 5 million, could not properly explain the unaccounted-for number of slaves who perished during the Middle Passage, those whose records were either not included in existing archival collections, or those whose numbers were calculated incorrectly.

Curtin’s estimate has also been disputed by other researchers who have made unsuccessful attempts to explain the disparity of 5 million slaves between the two researches conducted by Fage and Curtin. Joseph Inikori’s research group increased the figures. Inikori’s estimate of 15.4 million has also been challenged by scholars, including Patrick Manning and Herbert Klein. In 1982 Paul Lovejoy revised the figures provided by Curtin and Inikori and suggested 11.689 million as a more accurate number. In 1991 Barbara L. Solow developed a new estimate lower than the numbers provided by Fage, Curtin, Lovejoy, and Inikori. She argues that about 8 million Africans were forced out of their communities into the Americas. Solow’s model of analysis has not been questioned by many researchers because its scope is limited mainly to British trading patterns in Africa as well as to labor and colonial issues.

Another critic of Fage’s model went beyond Curtin’s interest in the number of slaves and developed a different thesis to explain other components of slavery. According to Walter Rodney, slavery in Africa was partially influenced by the Africans’ long tradition of domestic and regional slavery between African communities. Rodney’s argument is that European capitalism

THE BENEFITS FROM SLAVERY—THE CHALLENGES CONFRONTING RESEARCHERS

The actual number of slaves who were taken from Africa to the Americas has been difficult to estimate for a variety of reasons. Beside the inconsistency in statistics, other debates have focused on the social and economic impacts of slavery on African societies and how African economic production has been affected by the population loss. Whether or not scholars agree that Africans benefited economically from the slave trade, there is ample evidence showing that African slave labor facilitated the development of the Americas and Europe as well.

Discussions and conclusions about African slaves in the New World are largely derived from empirical data, which include archival materials, court records, newspaper articles, shipment entries, and port registers. Researchers are limited to slave records that are largely housed in European and North American archives because African institutions did not have most of the

resources needed to generate these archival materials between 1400 and the 1800s.

Paul E. Lovejoy argues that slavery was more deeply embedded in African institutions than past scholarships have emphasized. Although various scholars have developed new theories and adopted complex quantitative approaches to explain the mass movements of Africans during the Middle Passage, their conclusions are limited to specific countries such as Brazil, various locations in the Caribbean, and some parts of Europe. According to Lovejoy, scholars have not been given the space they deserve to examine slavery in Africa because of the way slavery in Africa in general is romanticized. Lovejoy believes that because of censorship by politicians and some African leaders, researchers are limited in terms of their access to archival materials that speak to the role that Africans played in transatlantic slavery.

—Kwame Essien

elevated slavery to a higher level by using its influences on Africans to fuel the rate at which slavery evolved from a domestic scene to an international level. As Rodney has stated, historian Paul Lovejoy in his recent work also shows that European demand for labor was the main driving force in the transportation of Africans. John Thornton's view differs from both Rodney and Lovejoy over the expansion of slavery in Africa. Thornton supports Fage's line of thinking and argues that the slave trade was a crucial part of war and conquest within Africa. Thornton believes that Europeans served as alternative trading partners who maintained their old trading traditions with Africans and who later decided to join the trading of Africans to the New World voluntarily. In other words, Thornton claims that Africans were not in any way forced into the transatlantic slave trade by Europeans. Regarding the conditions of slaves in Africa and the Americas, Lovejoy believes that slaves in Africa were also subjected to strenuous working conditions with little or no freedom. Lovejoy claims that slavery within Africa was as brutal as it was in the New World.

Another major problem facing researchers is their inability to agree on the extent to which the transatlantic slave trade affected Africa's development process. Rodney believes that the slave trade affected African economic systems. He argues that to understand the problems of African economic crises, we have to turn our searchlights to the period of transatlantic slave trade when Africa lost its manpower to the outside world. Inikori holds the same view as Rodney. Fage, on the other hand, does not agree that the transatlantic slave trade is one of the causes of African economic stagnation.

There are contradictions in the number of slaves taken from Africa to the Americas, how many Africans lost their lives within Africa during this period, and how many Africans perished during the Middle Passage. Researchers have argued and shown that the enduring legacy of slavery has influenced sociopolitical and economic conditions in many African societies. Lovejoy claims that slavery in Africa was transformed largely by external forces such as capitalism, but at the same time its growth was weakened on the local level by abolitionist projects in the

nineteenth century. The fact remains that the transatlantic slave trade led to the forceful migration of millions of people out of Africa and the depopulation of some parts of Africa, including, for example, Great Popo, located in the modern Republic of Benin.

The Experience of Enslavement—African Views

African views on the experience of enslavement between 1450 and 1770 offer a variety of perspectives and provide evidence for the fact of local institutional and individual adaptations to changing global conditions. Since for many participants in the slave trade enslaved Africans were perceived as commodities, these perspectives contrast sharply with the views afforded by the world historian's reliance on economic records alone. Instead, enslavement was perceived as a ritual or judicial consequence, a transformational social status, a response to environmental crisis, and an avenue to the political and economic empowerment of others.

Enslaved Africans were not uniform groups. Their diverse status, gender, religion, age, and peculiar individual circumstances of enslavement reveal the diversity of historical contexts. Many of the views of enslavement differed according to the origins of the condition of enslavement. Some enslavement occurred as a consequence of

kidnapping or capture in warfare. Other experiences of enslavement were imposed by social or political elites as judicial punishment or the exercise of harsh forms of political control under oppressive regimes. In order to remove undesirable political or social elements from the protection of kin groups, enslavement was viewed as a kind of judicial separation from the rights and obligations of the social fabric.

The views of African elites generally provide justification for the sale of war captives. Because enslavement was frequently state policy, the perspectives of African elites relied on institutions of slave acquisition and distribution to shore up political power. Annual slave raids and customary payment of tribute in slaves helped to legitimate the political power of rulers as measured in control over people. Religious institutions such as ancestral sanction through divination and oracle pronouncement also helped some elites consolidate power and eliminated potential threats from subversive elements from within society.

Viewed from the perspective of African families, the rationale for enslavement differed according to the prevalent social organization. In patrilineal societies, men wanted slaves as dependents precisely because they would have no kinship affiliation and no competing labor obligations. In matrilineal societies, slaves could be incorporated into the social network and provide an alternative means to accumulate and inherit wealth, avoiding obligations to sisters and maternal uncles. On the other hand, the enslaved could be assimilated into a family or household through marriage for protection. From Mali to Mozambique, the practice of self-enslavement reveals African views that enslavement could also be temporarily adopted as a survival strategy in times of crisis. For example, during the severe drought of 1738–1756, a significant percentage of the population of Timbuktu initiated self-enslavement to avoid starvation. Among the Sena, a ritual breaking of a pot initiated a form of dependency between the self-enslaved and a wealthy household, whose father became the father of the enslaved person, who was most often a young child.

African views on the experience of enslavement also depended on religious perspective. For many African Muslims, enslavement was a

proper method of conversion of unbelievers to the faith. Between 1500 and 1800 the Muslim trade (combining the Saharan, Red Sea, and Indian Ocean routes) accounted for between 25 and 40 percent of the slave trade. The legacy of enslaved Ethiopians in Deccan, India, produced a widespread perception that the enslaved could expect to find opportunity in the Muslim world, where slaves might become kings despite slave status. African poets and scholars alike celebrated war (jihad) as protecting future generations through triumph over the infidels. However, Ahmed Baba's treatise on slavery (1614) suggests that not all enslavement was considered legitimate. Baba condemned the Hausa states for selling Muslim war captives from another rival Muslim state.

By the eighteenth century the political economy of many states relied on official slave raids, and enslavement was perceived to be a function of the state. For example, in the eighteenth-century Oyo state, royal slaves resided in the palace. They served as administrative officials collecting taxes, and enslaved women might be members of a harem, while enslaved men might be members of the cavalry. Often originating from North Africa, the enslaved outsiders were afforded higher status because they were also Muslim.

Enslaved soldiers were commonplace in many African states. Their expected roles were predatory, and they sometimes even owned slaves themselves. War and plunder produced massive enslavement in the power vacuum left behind after the disintegration of the Kongo in the second half of the seventeenth century. The creation of Imbangala war bands enhanced the region's political instability and produced massive waves of enslavement. Invented rituals of sacrifice and cannibalism of the enslaved caused central Africans to fear capture and offer their own slaves in tributary payment to the Imbangala warlords.

The threat of violence was inherent in systems of enslavement in Africa and the African diaspora. An early eighteenth-century drum praise title of the ruler Mingi warned that if a slave runs, he is as good as executed. Leaders showed little mercy, so resistance was perceived as a desperate attempt to alter one's circumstances. Although the enslaved African Olaudah

Equiano, an Ibo kidnapped in the Bight of Benin in 1755, claimed that there was little difference between the appearance and labor of enslaved and enslaver in African societies, there is evidence to the contrary. The enslaved status could be broadcast by marking a victim, with scarification, hairstyle, and dress, rather than skin color distinguishing their different status and lack of kin group rights. In Caribbean and North American plantation societies, the practice of punishments in the form of torture, dismemberment, or death did not completely quell rebellions and resistance, ultimately suggesting the deafening desire of the enslaved to escape his or her fate.

Other early African views of the experience of enslavement may also be found in undated oral traditions, proverbs, and place-names. For example, a Nembe proverb warned that "one who buys a slave does not buy his mind." As the eventual slave narratives of the late-eighteenth-century abolition era would confirm, the enslaved Africans were not only commodities but were also people whose loyalty, status, and productivity proved invaluable to the foundations of the modern world.

The Indian Ocean Slave Trade

While the Atlantic slave trade of the early modern period is well known, historians have given less attention to the slave trade of the Indian Ocean. Trafficking in human chattel had taken place across the Indian Ocean since ancient times, although the sheer numbers of people enslaved never approached the totals attained in the Atlantic slave trade at its height in the eighteenth

Map of East Africa, Madagascar, and the Indian Ocean, after Jan Huyghen Van Linschoten, 1596. (Stapleton Collection/Corbis)

century. Yet, Indian Ocean slaving was often more complex, involving multiple sources and methods of supply, intricate international financing, and many different types of slave markets.

There are reports from ancient Rome of slaves taken from India, specialized entertainers, being sold or given away as diplomatic gifts, but the origins of the Indian Ocean slave trade really lie with the extension of Arab maritime trade from southern Arabia and the Persian Gulf ports to East Africa, India, and the islands of Southeast Asia. Slavery played a key role in the rise and growth of the Swahili trading posts, which dispatched thousands of African slaves to the Middle East and western India during the medieval period. At roughly the same time, a brisk overland trade in Indian slaves developed during the Turkish conquest of India in the eleventh through thirteenth centuries. Patterns of slave taking and long-distance slave trading thus were well developed by the time the Portuguese reached the Indian Ocean in 1498.

Portuguese navigators discovered the maritime route to the Indian Ocean as a result of their explorations along the coast of West Africa after 1415, at the same time developing a small but important slave trade between Africa and southern Europe. Thus, when these sailors reached the Indian Ocean, they were no strangers to the procedures and potential profits of slaving. Portuguese conquests along the Swahili

Coast of East Africa during the 1500s, especially their early victories, resulted in the enslavement of thousands of captives. Captured Muslims who could not ransom themselves were sold into slavery by the Portuguese. When Tristão da Cunha, one of Afonso de Albuquerque's officers, sacked the Somali town of Barva in 1518, for instance, the Portuguese chronicler Duarte Barbosa noted that he "carried many into captivity."

After the initial spate of conquests, the influx of war captives was replaced by a more permanent system of slaving. Extending a network of trading posts into the interior of Africa along the Zambezi River, Portuguese and Indian merchants traded for both gold and slaves, the latter mainly captives taken in local wars according to Jan Huyghen Van Linschoten, a Dutch priest who worked as an official of the Estado da India in the late sixteenth century. Portuguese traders also purchased slaves at Mombasa and Sofala and at smaller ports, usually operating under a special license from the Portuguese Crown. Slaving in East Africa under Portuguese domination, however, was never entirely dominated by European interests. Arab slavers and their African Muslim kinsmen continued to control the inland slave trade routes, while merchants from the region of Gujarat, in India, financed slaving expeditions into the interior. Long-distance slave raiders collected captives among the stateless peoples of the Great Lakes region of Africa and beyond, transporting them to the coast through grasslands belonging to Bantu groups such as the Nyamwezi, who demanded and received tribute from passing slave convoys. Before leaving the Swahili coast, slaves were sold to the Portuguese, branded as royal property, and baptized by Roman Catholic missionaries.

The destination of most African slaves purchased by the Portuguese was the Rua Direita, the slave auction yard at Goa, the Estado da India's headquarters on the west coast of India. There are several contemporary descriptions of slave sales at Goa during the sixteenth and seventeenth centuries, and these depict many of the slaves who arrived at Goa as malnourished, sick, and scarcely alive. Buyers examined captives carefully before purchasing. Somali traders from Mogadishu often purchased slaves from Mozambique for sale at Aden, doubtless

► THE FULL SCOPE OF THE INDIAN OCEAN SLAVE TRADE

The Portuguese took African slaves with them wherever they traveled in Asia, to the Spice Islands of what is now Indonesia and even to Macau on the coast of China. When the Dutch and French entered the Indian Ocean in the late sixteenth and early seventeenth centuries, they took over existing slaving routes as they assimilated the Estado da India's seaborne empire piecemeal. The Dutch diversified slave trading in the Indian Ocean, transporting Malay slaves—usually exiled prisoners—from Southeast Asia to Ceylon, India, and the Cape of Good Hope. At the same time, the Dutch East India Company sold Indian slaves—famine refugees from Bengal and Tamil Nadu who sold themselves or their children for food—at Batavia and other places in the East Indies. The French, for their part, focused on shipping African slaves from Mozambique and Madagascar to the island planta-

tion colonies of Mauritius and Bourbon and also to Pondicherry, the Compagnie des Indes's headquarters in India, where slaves were employed as domestic servants. The British also transported African slaves to India, especially to their outposts on the west coast of Sumatra, and although slavery was never a major component of the company's business, company-owned gangs of slaves are referred to in British records well into the 1770s. Indeed, during the Anglo-French Wars of the 1750s and 1760s, both the British and French employed hundreds of African slave-soldiers in India alongside their own European troops and Indian mercenaries. Malay slaves sent to Cape Town by the Dutch meanwhile played a significant role in the development of Cape Colony, forming a small but cohesive, primarily Muslim, community of Asian freedmen.

—James Hoover Frey

attracted by low prices. Van Linschoten informs us that “Caffres” (Kaffir, the Arabic term used to describe pagan Africans) could be had for only two or three ducats.

African slaves played a key role in Indo-Portuguese colonial society. By the late 1600s nearly 20,000 slaves lived in Goa, outnumbering the European residents and forming a substantial part of the city's entire population. Almost every Portuguese or Indo-Portuguese family owned a retinue of slaves, sometimes as many as 30 or 40, and intermarriage, or at least biracial sexual liaisons, seem to have been common. African women employed as nurses in Portuguese homes often became the mistresses of their owners either by choice or by force. However, Goa shared the tradition, established in other Portuguese slave-holding colonies, of granting freedom to pregnant slaves and their offspring. African men, meanwhile, found a niche for themselves as the attendants of *fidalgos*, or colonial aristocrats. A great many slaves, in fact, were employed by the Portuguese as personal bodyguards, soldiers, and occasionally hit men in gang-style faction fights between European officials. Other African slaves at Goa acquired new skills, becoming secretaries, musicians,

and craftsmen. One slave, Miguel, took Holy Orders and eventually rose to the position of vicar of the Convent of Santa Barbara in Chimbél, earning an advanced degree in theology in 1670. In fact, the Convent of Santa Barbara became a sort of center for African clerics within the Portuguese ecclesiastical hierarchy, although most of these individuals were not slaves but instead were the sons of the rulers of Mwenemutapa. Finally, the Estado da India itself also owned slaves, employing them to row galleys and work in gunpowder mills.

Most of the forms of oppression and cruelty that flourished in other slave-holding societies, such as Brazil, also were present in the Estado da India's enclaves. The movement of slaves and their activities were closely monitored. Infractions were punished in various ways, from the imposition of stiff fines to flogging, exile to the galleys, or even death. Most of the violence directed at slaves, however, was casual and unofficial, involving privately administered beatings that led to death and injury so frequently that the Church complained on several occasions. Slave revolts were rare but not unknown, and on a small scale African runaways were able to set up maroonlike renegade settlements, especially

in the rugged jungle-covered terrain of northern Kanara, not far from Goa, where some of their descendants still live today.

Maroon Societies—Colonial Mauritius

Located in the middle of the Indian Ocean, the island of Mauritius was first colonized by the Dutch in the seventeenth century. During their brief control, the Dutch imported slaves from Madagascar, creating a slave colony on the island. When the French took control of Mauritius at the beginning of the eighteenth century, they continued to use slave labor and imported a massive number of slaves to work on sugar plantations. Slavery would not end on the island until the British (who ruled there from 1810 to 1968) abolished the practice in 1835 and turned to indentured Indian laborers

as a workforce. Yet throughout Mauritius's status as a slave colony, slaves escaped to avoid harsh working conditions and abuse, visit family on other plantations, live in freedom, or travel home. These fugitive slaves were known as maroons.

Colonial authorities, from the Dutch to the French to the British, never were able to completely stop slaves from escaping, and maroons were a permanent presence on Mauritius during these years. Maroons not only deprived plantations of labor and money but also jeopardized the stability of a slave society. Fugitive slaves acted as symbols of resistance and created fear among slaveholders. Colonial authorities saw marronage as not just an individual act of resistance but also as the potential catalyst for a colony-wide rebellion that could lead to the overthrow of colonial control of Mauritius. Acts of arson and pillaging augmented these fears. In addition, most maroons were adult males, which added to a racial fear of white women being kidnapped and raped. In the early 1700s, authorities estimated that 3 percent of slaves had become maroons. But by the 1770s that number swelled. Slaves accounted for 75 to 85 percent of the population of the island, and with a desertion rate of now nearly 5 percent a year, this meant that there were thousands of maroons beyond colonial control. By the 1820s, 11 to 12 percent of the slave population were deserting every year. To deal with this threat, Mauritian authorities designed harsh, repressive measures. Slaves were at times shackled in chains, and armed parties hunted down fugitives. Captured maroons lost ears and were branded, while repeat offenders were executed.

Still, despite these methods, maroons continued to exist on Mauritius. While many maroons wanted to escape slavery, others ran away to maintain personal contacts with friends and family. Maroons often fled to remote areas, particularly to the center and eastern parts of the island, taking refuge in the tropical forests. Usually maroons remained mobile, traveling in small groups to avoid detection. As slave plantations expanded and cultivated more land in the center of the island, tropical forests shrank, forcing maroons to flee into the mountains and the volcanic caves and tunnel systems on Mauritius. While some avoided capture for only a few days, others lived for years in freedom. However, since most

Le Morne, Mauritius. (Lawrence Banahan/StockphotoPro)

► THE FUGITIVE SLAVES OF TROIS CAVERNES

The use of regularly armed hunting parties meant that Maroons could no longer hide in the forests of Mauritius. Instead they retreated into inaccessible and remote places such as the cave system at Trois Cavernes and the massive extinct volcano of LeMorne. In these areas, Maroons established small communities. Recent archaeological evidence, such as shackles and food pits, reveal that the lava caves of Trois Cavernes housed 54 Maroons before they were captured and executed in the 1780s. Even more slaves took refuge in

the rugged mountains of Le Morne throughout much of the eighteenth century. Long after slavery and Maroon communities ended, oral traditions on Mauritius have helped to fix Le Morne as a place of slave resistance. In 2008 it was made a UNESCO World Heritage site as a “symbol of the slaves’ fight for freedom, their suffering, and their sacrifice,” to the peoples who were enslaved on Mauritius from across the Indian Ocean.

—Thomas Anderson

maroons escaped alone or in pairs, and given the small size of Mauritius and expanding plantations, few viable maroon communities were established. An exception was the mountain refuge of Le Morne, where the inaccessibility of the rugged mountain helped protect maroons.

With the end of slavery in 1835 and the turn to indentured Indian labor, a new Mauritius emerged. Mauritius became a creole community with an identity drawn from a mixture of the legacy of slaves, free Africans, Indian laborers, white landowners, and maroons. Today maroons have become a proud symbol of freedom and resistance to slavery on Mauritius.

Maroon Communities in the Americas and Caribbean

While millions of Africans were introduced into the Americas via the slave trade, not all of them remained in the institution of slavery. Some were manumitted by their masters, but others chose to gain freedom on their own terms by escaping

the plantations and forming their own communities. These refugees were known as maroons in English, Marron in French, Cimarrón in Spanish, and Quilombos in Portuguese. They formed communities that existed outside of mainstream society and were autonomous from their former masters. The size of these societies ranged from as small as a few people to others that contained thousands. These communities spanned the entirety of the Americas, crossing culture and language barriers. While this makes it difficult to create generalities about life in these communities, some common aspects can be found among all of these groups.

In 1502 Governor Ovando sailed to Cuba in the hopes of reviving the flagging colony. On that ship he carried a few African slaves, one of which “escaped to the Indians” as soon as the ship docked. This refugee became the first maroon, or escaped slave, to attempt to live outside the institution of slavery in the Americas. The maroons were the main source of resistance against slavery and the slave owners as well as the most visible one. Those maroons who were apprehended by the authorities were usually punished with torture or even death. However, certain communities posed such a strong threat to slave owners and cities that treaties were negotiated whereby the maroons were allowed autonomy in exchange for the end of hostilities. These cases were few and far between. Normally the maroons were crushed by the plantation owners, but a new community would quickly spring up in the old one’s place.

► CONTEMPORARY DESCENDANTS OF MAROONS

In Mexico, the maroons of the Costa Chica, located in the states of Guerrero and Oaxaca, are descendants of Africans who began escaping in the late sixteenth century from Spanish cattle plantations on the Pacific coast. Currently in this area of Mexico the Afro-Mexican culture is still alive and vibrant. Likewise, Colombia is home to a vibrant ex-Maroon community called Palenque de San Basilio, located near the Spanish port city of Cartagena de Indias, once the center of the Spanish slave trade in South America. The residents of Palenque San de Basilio are descended from slaves who escaped Spanish plantations. Today in Palenque the residents speak *palenquero*, a Spanish-fused Creole rooted in elements of the Kikongo languages from the Congo and Angola.

—Kwame Dixon

In order to be viable, maroon communities required certain conditions to be met. The first and most important was remoteness. The communities that survived were the ones that existed in highly inaccessible areas such as jungles, swamps, and canyons. Just as important as the location was the ability for the residents to conceal themselves. Often, they were able to use their surrounding environment to either disguise the paths leading to their encampment or to create booby traps to entrap any intruders. In addition to protecting their home encampment, maroons also honed their skills in guerrilla warfare. Their use of the environment in fighting off the colonists was advantageous, as the colonials were trained in the traditional European style of fighting, which only worked well in the open battlefields, not in the jungles of South America. Finally, a viable community needed some sort of means to feed its people. Many relied on swidden agriculture, although most stole directly from the nearby plantations. In addition, they again used the environment around them for sustenance by hunting, fishing, and eating wild nuts and berries.

Many of these techniques that the maroons used for survival were learned from the indigenous population and were perfected on the plantation before their escape. However, despite all of their achievements, the maroons remained

reliant on the plantations to some extent because of their inability to manufacture guns, tools, pots, and cloth. This meant that they were forced to either steal these commodities from plantations and cities or had to engage in clandestine trading relationships with people living on the plantations. The maroons also participated in relationships with local indigenous tribes. Sometimes, the proximity of the two groups resulted in disputes and evolved into all-out wars, but there were also cases of the two groups fusing into one. Examples of this fusion can be seen in the Miskito people of Honduras, who began using maroons as domestic servants in the seventeenth century. This relationship resulted in intermarriage between the Miskito and the maroons, but the Miskito remained the genetically dominant of the two. Conversely, the Island Carib also began by using the maroons as domestic servants, but the Afro-Americans became the genetically dominant of the two. While these fusions were not the norm, there were cases of maroons taking indigenous wives in cases where their societies had shortages of women.

It was important for maroon communities to ensure that new recruits did not pose any kind of a security threat. There was a real danger that someone posing as a runaway slave could actually be serving as a spy for the local slave owners or that new recruits might decide to return to their masters and reveal the location of the maroon community. Therefore, communities took precautions to ensure that their security was not breached. Some took their new members through meandering paths so that any who left would not be able to find their way back. Some, such as the Palmares in Brazil, required new members to serve as domestic servants until they were able to capture a replacement. In others, new members were required to undergo a probationary period in which they could not leave the village for a certain amount of time. It seems that most communities punished desertion with death. In addition, any internal strife was dealt with harshly, many times with death.

As for social structures, men greatly outnumbered women in most maroon communities. The first slaves brought to the Americas were mostly male, as they were physically stronger and better able to do the work expected of

them. In addition, it was easier for men to escape than women, which created a shortage of women among maroons. Finally, polygamy was practiced among the more important men, making the shortage of wives even greater. In some cases, maroon men tried to ameliorate the problem by capturing indigenous women for brides, but it was not enough to increase the supply of available wives. As a result, strife was sometimes high as men vied for the small number of available women. The penalty for adultery was usually death; however, there were other solutions to these issues. One example of this can be found in the Leeward maroons of Jamaica. They allowed men to share women, although there were strict rules concerning these practices, even regulating the number of nights each man was allowed to spend with a woman.

Even though most maroon communities were smashed by the plantation owners that surrounded them, some still managed to survive. In fact, some of these communities have survived into the present day.

Forced Resettlement in Gunpowder Empires

The gradual expansion of the Ottoman empire and Safavid Iran was accompanied by a process of forced resettlement through which populations were displaced from their habitat and/or economic activities and relocated to another site to reestablish their productive activities and community life. The Ottomans sought this

state-organized mass resettlement policy, known as *sürgün*, in almost all newly conquered territories and applied it to an individual, a group, a tribe, or even whole populations. This policy had three main purposes: removal of recalcitrant groups or communities of questionable loyalty, securing authority in a given region, and promoting economic life in regions and cities. Thus, nomadic Turkomans were periodically resettled from eastern Anatolia into the Balkans, where they protected Ottoman authority and raided Hungarian and Habsburg territories. At the same time, European technicians, captured in wars and raids, were forcibly relocated to the Ottoman empire, where their skills were used for the benefit of the sultans.

Forced resettlement of civilian populations played an important role in populating Ottoman cities with the talents needed to make them develop and prosper. Following his conquest of Istanbul (Constantinople) in 1453, Sultan Mehmed II the Conqueror (el-Fatih) sought to restore Istanbul to its former greatness and encouraged and often forced Armenian and Greek Christians and Jews to resettle in Istanbul; by the end of his reign, the city was again a thriving metropolis of over 100,000 people. His successors continued this policy and, in 1514, following his decisive victory over the Safavids, Selim I resettled approximately 2,000 craftsmen from the Safavid capital of Tabriz to Istanbul. After the Ottoman conquests of Belgrade in 1521 and of Buda in 1524, thousands of Christians and Jews were transported for settlement in the Ottoman cities of Edirne, Izmir, Salonika, and Istanbul. Similarly, the Ottoman conquests of Rhodes in 1523 and of Cyprus in 1571 were followed by orders to resettle hundreds of Jewish families from Palestine and Syria to revive the newly acquired provinces, while Turkish nomadic tribes from Anatolia (up to 20,000 people) were transported with their cattle and their implements to maintain Ottoman authority on the islands.

The Safavids also regularly practiced forced resettlement, but the scale of their endeavors often dwarfed those of the Ottomans. The rulers of Iran actively pursued resettlement policies in northern and western Kurdistan, where tens of thousands of Kurds were removed and dispersed throughout the empire. This policy was

implemented in earnest by Shah Tahmasp (1524–1576), who during his conflict with the Ottomans began systematic destruction of Kurdish communities and resettlement of Kurdish tribes to eastern Iran, even as far as the Hindu Kush mountains of present-day Afghanistan. These isolated Kurdish communities, surrounded by hostile local tribes, eventually became bulwarks of the Safavid authority in the region. The resettlement policy arguably reached its height during the reign of Shah Abbas (1588–1629), who practiced it on a vast scale. Iskandar Bayg Munshi, the shah's court historian, in *Alam-ara yi Abbasi* described how the shah commanded Kurdistan to be laid waste and the population rounded up. Those who resisted were massacred, property was destroyed, and the prisoners were driven southeast.

Shah Abbas also targeted the Christian communities of Georgia and Armenia. In 1614–1617 he launched several expeditions against eastern Georgian kingdoms, razing numerous towns and resettling up to 150,000 Georgians and 150,000 to 200,000 Armenians into south-central Iran, where they helped to develop the local agriculture and industry; their descendants still reside in various Iranian provinces, mainly in Fereydan.

Similarly, in Armenia, Abbas removed between 250,000 and 300,000 Armenians for settlement in Iran. Thousands died during the harsh forced move, and survivors were settled in Iranian Azerbaijan, where other Armenians had settled earlier; some ended up in the Mazandaran region and in the cities of Qazvin, Mashhad, Hamadan, and Shiraz. The wealthy Armenians of Julfa in Armenia were brought to the Safavid capital of Isfahan, where they were treated better and were granted relative autonomy and privileges. Many Georgians and Armenians enjoyed a high status in society and at the court, playing an important role in the revival and development of the Iranian economy, agriculture, and commerce. Abbas also used the resettled population to develop a corps of royal troops known as *ghulamani khassa* (also known as *qullar*), which he used to create a power base internally independent from the Qizilbash tribes. Yet although the subsequent shahs relied on these ghulam troops, they were not always successful in containing them. Thus, Shah Ismail II spent almost 20 years under virtual

house arrest due to power gained by Georgians at the court and in the harem.

Shah Abbas's successors did not continue his policy of forced resettling of the tribes, and the distribution of tribes remained relatively unchanged for the next century. The policy, however, resurfaced during the reign of Nadir Shah (1736–1747), who pursued it with great vigor. To deal with the rebels and undermine Ottoman influence, he depopulated the provinces of Azerbaijan, Iraq, and Kurdistan, transporting many tribes to northeastern Iran, particularly in Khurasan. The resettlement and concentration of tribesmen in Khurasan served a variety of purposes. It divided and weakened tribes that might otherwise have opposed Iranian authority or supported the Ottomans. It also defended Khurasan, Nadir's power base, against any foreign threats, while the selection of young men from among the settlers to serve in Nadir's army not only provided him with superb cavalry but also made them hostages for the good behavior of their relatives elsewhere.

Forced Migrations—The British Transatlantic Slave Trade

English participation in the transatlantic slave trade went back to the voyages of Sir John Hawkins (1532–1595). However, in the sixteenth century and the first half of the seventeenth century, the English played a relatively minor role compared to the Portuguese, Dutch, and French.

English participation grew after about 1660, and in the eighteenth century the British dominated the trade, shipping more slaves than all competing European nations combined until Parliament abolished the slave trade in 1807. Although total figures will always remain speculative, some scholars have estimated that in the period of British dominance slightly over 3.4 million slaves were shipped from Africa in British and British colonial vessels. Colonial vessels only shipped about 5 percent of the total.

British slave traders worked the so-called triangle trade. Although the reality was often more complicated, the triangle trade referred to the export of British-manufactured goods to Africa for slaves, the importation of slaves to the Caribbean for sugar and other agricultural goods, and the return of these colonial products to Britain.

The areas on the Atlantic coast of Africa from which traders obtained slaves varied. A consistently major source of British slaves was the Bight of Biafra, where the British managed to virtually exclude European competitors. Over the course of the slave trade, the Bight of Biafra supplied about a third of British slaves. Other areas where the British obtained slaves included the Bight of Benin, the Gold Coast, Senegambia, and Sierra Leone. Britain maintained coastal bases for the slave trade where slaves were assembled before being boarded. Bases could only be held by agreement with local rulers, sometimes drawing British slavers into African politics. Competition between European slave-trading nations for bases could be fierce, particularly in time of war. (War generally saw diminished slaving activity, as the seas grew less safe and the Royal Navy's demand for sailors increased.) Like other slavers, British traders bought a majority of male slaves, who would fetch a higher price in American slave markets, although the ratio of male to female slaves varied according to period and region of Africa. On average, about two-thirds of the African slaves carried on British ships were male. Young adult slaves were more valuable than older people or children, and most slaves were between the ages of 15 and 30.

Conditions on slave ships were notoriously overcrowded and disease-prone, with Africans exposed to European diseases like smallpox and even the common cold to which they had little

➤ THE ROYAL AFRICAN COMPANY

Although English slave trading began with individual captains, the state sought to regulate it, and trade with Africa in general, through a series of chartered companies. The most powerful and long-lasting of these was the Royal African Company, chartered in 1672 with the grant of a 1,000-year monopoly over trade with Africa not limited to slaving, although this quickly became the company's chief business. However, the lure of high profits drew illegal competitors. Authorities in the Caribbean British colonies, desperate for slaves, supported the interlopers against the company's monopoly, making it virtually impossible to enforce in America. In 1698 Parliament abolished the monopoly, requiring only that independent traders pay a 10 percent fee to the company on goods exported to Africa. Even this requirement was set to expire in 1712.

The independent traders proved more efficient than the Royal African Company and quickly dominated the trade while greatly expanding it. The company continued to control the bases on the West African coast from its main base at Cape Coast Castle in modern Ghana but carried on little of the actual trading. By 1730 the company had virtually abandoned slave trading and was dissolved in 1752.

—William E. Burns

immunity. Since slave groups were often assembled from widely distant places in Africa, they could also spread local African diseases among themselves. In addition to dying from disease, slaves committed suicide by starving themselves or jumping overboard if they were freed of their shackles, and on a few occasions they rebelled and attempted to seize control of the ships. Mortality on the Middle Passage from Africa to America varied tremendously between voyages, but the overall tendency across the decades of the slave trade was to decline. In the history of British dominance of the trade, approximately 13.2 percent of slaves died in the Middle Passage.

The principal market for slaves carried in British vessels was the British colonies in the Caribbean, particularly Barbados, Jamaica, and the Leeward Islands. British victory in the Seven Years' War (1756–1763), which led to the

acquisition from France of Dominica, Grenada, St. Vincent, and Tobago, made those areas major markets for British slavers. The harsh demands of sugar cultivation meant that few slaves lived long lives and that enslaved women were often infertile, maintaining a constant demand for slaves in the sugar islands. Another major group of markets was the British colonies in North America, particularly South Carolina after plantation society was established there from Barbados in the late seventeenth century. The tobacco colonies of the Chesapeake, although dominated by slave-worked plantations, did not make as many physical demands on their slaves as did the sugar islands or rice-dominated South Carolina and had a more self-sustaining population with less demand for new slaves from Africa. Georgia was a major slaving market after about 1750. A third group of markets was the colonies of other European nations. After the gaining of the *asiento*, the right to trade with Spanish America, in 1713 following the War of the Spanish Succession, the British shipped thousands of slaves to Spanish colonies. Even the Caribbean colonies of Britain's great eighteenth-century rival France, unable to satisfy their demand from French traders alone, bought slaves from British shippers.

African Muslims in the Americas

The transatlantic slave trade, which led to the forced migration of millions of Africans to the Americas, depended on an extensive supply of slaves typically from western and central Africa. The extraction of Africans from these regions,

which through trade networks established in prior centuries had developed connections with the Islamic world, suggests that Muslim Africans entered the Americas in the tens of thousands from the sixteenth to the eighteenth centuries. Historical evidence suggests that African Muslims who were brought as chattel slaves to the Americas retained their religion, thus making them the first Muslims to enter the New World. Moreover, historical evidence illustrates that Muslims were chosen as slaves by slaveholders for particular tasks, given their levels of education, piety, and appearance, and that they were not used for heavy labor but rather for more managerial and domestic responsibilities.

As early as the ninth century, Islam had expanded south of the Sahara into sub-Saharan Africa through the efforts of Arab and Berber merchants. The association of Islam with trade made many African leaders and elites more amenable to conversion, although they retained many aspects of local religions syncretized with Islamic characteristics and practices. By the sixteenth century, Islam had made considerable inroads into west African societies as the transatlantic slave trade was developing into a mainstay part of the regional economy. Most of the slave supply areas in western Africa, from Senegambia to the Gulf of Guinea, relied on the constant supply of slaves from adjacent regions that had experienced differing levels of Islamic influence. Senegambia in particular had a considerable population of Muslims, which while not a majority was still substantial in relation to the non-Muslim community. Many of these regions, such as the Gold Coast (modern-day Ghana), actually experienced an expansion of Islam during the development of the transatlantic slave trade.

The British, Spanish, and French purchased many of their slaves in western Africa and brought them in substantial numbers to their American empires. The Spanish and French imported Muslims to their colonies in Florida and Louisiana, respectively. Based on newspaper accounts in which their regions of origin and Islamic names are recorded, evidence suggests a Muslim background. In British North America, substantial numbers of African Muslims were purchased by slave owners. Slaves from Senegambia and Sierra Leone, known collectively as Mandingoes by

➤ AFRICAN MUSLIMS IN BRAZIL

African Muslims, while few in number given the substantial amount of black African slaves imported into Brazil by the Portuguese during the sixteenth through the eighteenth centuries, were nonetheless the first Muslims in Latin America. Sugarcane cultivation on large plantations created the need for the Portuguese to bring in increasing numbers of slaves to work what was an extensive harvest and processing industry. While most of the slaves brought were from Angola and the Congo, which were not particularly Muslim areas, Muslims from the Swahili coast and the Gold Coast regions were part of this forced migration. Much like African Muslim slaves in North America, Muslim slaves in

Brazil were treated differently than non-Muslims and were given not only relatively less strenuous employment but also religious privileges, given their literacy. Moreover, while African Muslims came from various parts of sub-Saharan Africa, mainly to the Bahia region of Brazil, they were seen as a single group by the slaveholders and thus were treated as such, creating a sense of cohesiveness over time. Though they were treated relatively better than non-Muslim slaves, African Muslims were nonetheless part of the transatlantic slave trade, which coerced millions of black Africans into forced labor in the Americas.

—Abraham O. Mendoza

slave holders, were preferred to other slaves from other regions, particularly in the Carolinas and Georgia. These slaves were preferred for their assumed subservience, work ethic, and skills. Advertisements for runaways also give a hint as to information related to ethnic and religious aspects of slaves. Muslim names, such as Mustapha, Sambo (which means Samba or second son), and Ibrahim, suggest to some historians the presence of Muslims in colonial America.

Many African Muslims were able to preserve aspects of their faith, such as being able to write in Arabic, maintaining their religious observances, and successfully passing aspects of their faith on to their offspring or converting other African slaves. Evidence suggests that slave owners held their Muslim slaves in high regard, often imparting them with oversight duties over other slaves and relying on their specialized agricultural skills (particularly in rice and indigo cultivation). As a result, some Muslim Africans, aware of their elevated position in slave society, looked down on their fellow slaves. As some Muslim Africans had distinctively different phenotypes than other black Africans, given differing levels of intermarriage with Arabs and Berbers, this provided another level of ranking within slave society whereby Muslims were associated with lighter complexions. However, over time the retention of Islam ebbed as slaveholders found it expedient to convert all their slaves to

Christianity en masse given the assumption that this would make them more accepting of their social condition. Nonetheless, some slaves were able to preserve elements of Muslim religious practices in their syncretized versions of African American Christianity. In spite of the development of a cohesive African American identity under slavery from multiple African identities, aspects of Islam were preserved in the cases of families and regions throughout the southern United States such as family names and diet.

Indian Ocean and Trans-Sahara Slave Trade

The movement of slaves across the Sahara, the Red Sea, and the Indian Ocean to the East is less

TRANS-SAHARAN TRADE, 9TH–19TH CENTURIES

well known than the transatlantic slave trade. The main requirement of slaves for the Americas was to produce sugar, coffee, tobacco, rice, cotton, gold, and silver for global markets. The drivers for the Indian Ocean slave trade, however, were more diverse. There are crucial differences between the dispersal of African slaves in the Atlantic Ocean and Indian Ocean worlds in terms of the time span, the demands being met, and perhaps most importantly the nature of interactions with the host cultures.

First, the African slave trade in the Indian Ocean has taken place over a much longer period of time. From the first century records of the *Periplus Maris Erythraei* (Periplus of the Red Sea), Arabs trading across the East African coast, indicate exported slaves from Somaliland

to Egypt. International trade, commercial enterprises, religious beliefs, and colonization were important forces behind this involuntary migration.

Second, the demand for slaves in the East was not driven simply by economic motives. African concubines and eunuchs, for example, did not yield monetary returns. The demand for soldiers and workers also propelled migration where bravery and loyalty of Africans was highly valued. In Asia, African slaves filled particular niches where they had earned a reputation as able soldiers, bodyguards, divers, jockeys, musicians, dancers, and entertainers, for example.

Third, African slaves moving eastward encountered older and more diverse cultures. These societies were colored by ancient philosophies and religious affiliations and had varied systems

of social organization and hierarchy. Out-marriage was encouraged, and many slave descendants were absorbed into existing kinship networks, though assimilation was always imperfect. Hidden habitats of the descendants of African slaves have contributed to their invisibility. While some descendants of African slaves are part of Afro-Asian communities, particularly in rural areas, others are blending into the multiethnic landscape of Asian cities. Today descendants of African slaves live in Turkey, Iraq, Iran, Dubai, Oman, Pakistan, India, Sri Lanka, Maldives, and Indonesia. African slaves were also taken to Afghanistan, China, Japan, and Malaysia. Slaves taken from the African continent to islands in the western Indian Ocean (Madagascar, Mauritius, Réunion, Seychelles, Rodrigues, Chagos, Diego Garcia) became creolized. Many of these islands were populated during the struggle between European powers for hegemony over the region and trade monopolies in the East.

In archival documents, Africans are referred to by several names, both ethnonyms and exonyms, such as *Habshi*, *Kaffir*, *Sidi*, *Zanj*, *Ghulam*, *Abd*, and *Barbaru* that conceal their ethnic origins. But if you take into account the duration of the movement, the various slavers involved, and the lands and people among whom the forced migrants settled, this is not surprising. Given that the continent was not called Africa throughout history, in Asia slaves or freemen from the continent were called by other names. For example, many slaves were perceived as arriving from Abyssinia (present-day Ethiopia, Eritrea, and Sudan). Therefore, many Africans were called *Habshi* (from *habashat*, a Semitic people in northern Tegray, Ethiopia).

Despite the circumstances of forced migration, the heights that some first-generation African slaves reached in the East are remarkable. This is epitomized by Malik Ambar, who ruled Ahmednagar (India) for the first quarter of the seventeenth century (1600–1626). Ambar, an Ethiopian slave, rose to prominence by defeating and invading the Mughal army. His tomb in Kuldabad (Maharashtra State) commemorates his gallantry and achievements both politically and socially. Ambar was not a one-off. There were other forced African migrants who reached the corridors of power in Asia.

For migrants, and particularly for those who move involuntarily, it is difficult to maintain their ancestral traditions and customs. Understandably, it has not been possible for African slaves to hold on to their languages, but their sense of rhythm and their musical traditions have not been erased. They remain embedded in the cultural memories of the descendants of African slaves.

Legislation passed by Britain in 1807 abolishing the slave trade in the Atlantic was not necessarily effective in the Indian Ocean. Nevertheless, the impetus from the Atlantic speeded up the process of abolition in the Indian Ocean. Abolition of slavery occurred at various times in different Asian countries and generally followed the British Emancipation Act of 1833. In terms of numbers involved, the easterly slave trade was not very different from the westerly movement. While estimates reveal that 13 million Africans crossed the Atlantic due to the slave trade between the sixteenth and nineteenth centuries, the estimates for the eastward trade are not very different. About 12.5 million Africans are estimated to have crossed the Sahara, the Red Sea, and the Indian Ocean between 800 and 1900 CE. The difference of the two migrations lies in the period over which the trade occurred. While the Atlantic slave trade was concentrated over four centuries, the easterly slave trade continued for millennia. We should question why such a significant movement of peoples has received so little attention. The economic unimportance of this trade and the extent of assimilation might partly explain this anomaly. But it is necessary to break this silence and try to unravel what happened on the other side of Africa. This will involve consulting material in archives and also conducting fieldwork among Afro-Asians.

Enslavement and Forced Migration in the Inca Empire

The Inca empire, known as *Tawantinsuyu* (or the “land of the four quarters”) to its inhabitants, was one of the largest empires of the ancient world. Originating in the central Andes, by the time of the Spanish conquest, only 150 years since its foundation, it stretched to include territories in the Pacific coastal region, Lake Titicaca in the Bolivian Highlands, the region of Quito in Ecuador to the north, the Argentinean pampas (grasslands) to the south, and parts of the Brazilian Amazon. The organization of the Tawantinsuyu rested on a very efficient system of production and redistribution of goods produced in the vastly different ecological niches of the empire.

The Inca empire took over the markets and preexisting trade networks, replacing them with a tight system of centralized redistribution. Land was allotted to family units depending on their specific needs. Agricultural goods as well as wool, used for clothing, were amassed in government storehouses and efficiently found their way to the different provinces. This way, every subject contributed to the economic life of the empire. There were exceptions, however, constituted by different categories of people (although the sources are not always consistent about this) who were serving the state directly, producing specific luxury goods, or attending to royal courts, kings, and temples. Although they are sometimes referred to as servants, their status as “royal employees” granted them a number of privileges, among which was the exemption from tribute. On the other hand, they were often taken away from their communities, losing any tie with their place of origin. As such, their role has been considered pivotal in the ideological creation of the Inca empire itself, which included a myriad of different ethnic groups.

A specialized class among these nonethnic members of the Inca empire was constituted by

the *camayo*. They played a major role in the production of pottery, but most importantly they were dedicated to supplying the emperor with luxury goods, such as fine textiles and gold and silver jewelry. The goods thus produced were exclusively owned and redistributed by imperial officials in order to create alliances among elite members in the provinces.

The most significant group was constituted by the *yanacona* (meaning “black” or “servant”), a male class who worked directly for the emperor. Duties included caring for the emperor’s living quarters as cooks, gardeners, and maids and even serving as litter porters. Some worked in royal private estates as farmers or cattle herders. Yanacona were loyal to the king even after his death. Some could be sacrificed and buried with him, while others remained to serve the cult of the deceased king. Yanacona could be given by the emperor to members of the lesser nobility, such as the ethnic provincial *kurakas*, as a gift and reward for their allegiance. Finally, yanacona were given to *huacas* (holy sites and temples) to perpetually serve the cult, prepare for celebrations, and receive pilgrims. In order to better attend to the cult, huacas often owned lands, used for agricultural or cattle purposes, that also were maintained by the yanacona. The large pilgrimage center in the Lake Titicaca region in modern-day Bolivia, where the Inca claimed to have originated, was allegedly served by 2,000 yanacona.

The female equivalent to the yanacona were the *aclla* (meaning “the chosen ones”), women who especially devoted their lives to serving the emperor or an imperial cult. They were in fact chosen from different parts of the empire because of their beauty and high-ranking position. Although they could perform some of the same duties as their male counterparts, such as working as maids in the palace or as farmers on the estates, they devoted most of their time to female activities, such as weaving and preparing beverages. The ones deemed to be more beautiful would dedicate their lives to the cult of the Sun, the most important deity in the Inca empire, and would not marry, maintaining a vow of chastity for the rest of their lives. Others would become wives of the emperor.

Finally, another fundamental aspect in the sociopolitical construction of the Inca empire

was the so-called *mitimae*, colonists forcefully replaced from distant provinces into newly conquered territories. Such displacements served a twofold function: they made a pragmatic use of human resources, employing labor where it was most needed, while at the same time reducing the risk of revolt. A newly conquered population was resettled in an area that had been under Inca rule for some time. The people would “swap” with already-integrated Inca subjects. While the new settlers always maintained their distinguishing dresses and customs, they assimilated into the imperial system by learning from other subjects. Yanacona and aclla, who as we have seen served important religious and economic functions, were themselves often times *mitimae*. This is an indication that the incorporation of foreign people into the larger imperial system was a central aspect of Inca conception of rulership.

Enslavement in the Aztec Empire

Information on slavery in Aztec society is fragmentary and often contradictory. While Spanish observers remarked numerous times on the existence of people sold in the market and coerced into working for a master, their status as

a separate social class is debatable; different circumstances, social or economic, could lead to a person's enslavement. Slavery among the Aztecs was not hereditary but instead was the result of punishment or even voluntary, and it was in some cases reversible. In Aztec society, these people were referred to as *tlacohtin*. Although their labor was forced, slaves maintained rights to get married (with another slave or a free person), maintain a household, and conduct business in the market. Their offspring were born free. Most commonly, the duties involved as slaves were related to maintaining the owner's house, although rarely would slaves be employed as farmers. Enslaved women performed characteristic female activities such as weaving and cooking. Female slaves were often exchanged as gifts and lived as concubines in the owner's household. *Tlacohtin* were mostly employed in the cities, where the commerce of slaves also occurred. The transaction into slavery occurred in the market and was supervised by a group of elderly people.

A common reason for becoming a slave was theft. Being caught in the act of stealing resulted in becoming a slave, most of the time to the person against whom the crime was perpetrated. If stealing involved destruction of property or if the robbery was conducted in a temple or in the house of a noble person, the perpetrator would become a slave to serve in the temple or in the noble house. According to some sources, however, if the stolen goods were returned or if the thief was somehow able to repay the stolen goods, then the thief could avoid being enslaved. On the other hand, in case of a repeated offense the perpetrator could be sentenced to death. Other crimes such as homicide and rape, usually punished with death, could sometimes lead to enslavement.

The most common reason for enslavement, however, was economic necessity. People who found themselves overwhelmed with debts could voluntarily sell themselves or their children on the market in order to repay their dues. This would most commonly occur with people addicted to gambling, such as the Aztec board game *patolli*, or the ballgame. Debt usually had to be paid with cloth. In the event that a person did not have means to give cloths, then he

or she would become available in the market for purchase. Merchants took advantage of famine during seasons of extreme droughts to enrich themselves with the trade of members of impoverished families. This was the case, for example, with the great drought that occurred in 1450–1454, when large quantities of people were sold in Tenochtitlan to the neighboring southern cities of Cuitlahuac, Mixquic, and Chalco, whose fertile *chinampas* (raised fields) provided the necessary food for all.

Unruly slaves had to wear heavy wooden collars not only to publicly ridicule their bad behavior but also to prevent them from escaping. If a slave repeatedly showed bad behavior, such as laziness or insubordination, then he or she could be sold as a sacrificial victim. Slaves condemned to death by human sacrifice were specifically sold on the market for this purpose. Finally, war captives could also be taken and sold as slaves. Their fate was, however, almost always that of serving as sacrificial victims during religious ceremonies.

A special form of slavery was constituted by the *buehuetlatlacolli* (which can be translated as “ancient fault”), a system by which a family was perpetually obliged to give one or more of its members as servants or maids to serve another family. Huehuetlatlacolli was abolished by the king of Tezcoco Nezahualpilli in 1505 in order to avoid excessive exploitation during a time of famine in central Mexico. The Aztec emperor Motecuhzoma II also abolished perpetual slavery in the following years.

Slaves could gain freedom by repaying the debt that brought them to slavery in the first

place. This instance was not that rare, given the fact that slaves were allowed personal properties, could have families, and could engage in trading or other economic activities. Female slaves could achieve freedom by marrying their owner. Alternatively, a male slave could become free by marriage if he was able to replace himself with another member of his family. Another way by which one could end enslavement was running away from the master in the market. If in so doing the slave accidentally stepped into human excrement, this would result in the end of captivity. Similarly, a slave could be free by escaping the master and finding refuge in the royal palace in Tenochtitlan. In both instances, no one could stop a slave from running. This was a crime that was in turn punished with slavery.

Politics and Statecraft

During the 300 years covered in this volume, while some of the world's political systems remained unchanged, in other regions there were major transformations as a result of political rivalries as well as religious and social upheavals. In Europe in particular, the existing political and economic order came under increasing challenges and led to the rise of new political systems. Yet political change was a long and complicated process and did not necessarily develop in the same direction. England and Holland, for example, made a gradual turn to constitutional monarchy, while at the very same time France embarked in the opposite direction as King Louis XIII and King Louis XIV laid the foundation for French absolutism.

By the late seventeenth century the first nation-states were formed in Europe. Unlike the rest of the world, which was dominated by the great empires (e.g., Ming China, the Ottoman empire, and the Safavid empire), in Europe empires dissolved with the rise of sovereign states composed of socially cohesive populations that shared a common language, religion, history, or ethnicity. Each state's emergence and development was greatly shaped by its relationships with neighboring states. These nation-states were characterized by their centralization of power maintained by efficient bureaucracies and protected by large modern armies. The nature of supreme authority, however, differed depending on the country. Although the majority of European states were monarchies (e.g., England, France, Spain, etc.), some such as Holland and the Italian city-states (e.g., Venice) were oligarchies controlled by merchants. The nation-states proved to be very resilient, flexible, and powerful political entities. Their rise was one of the leading factors in Europe's emergence as a global power. Other states either emulated them—thus Russia's rapid modernization under Peter the Great in the 1700s—or kept them at arm's length, as did China and Japan, both attempting to close their borders to European influence.

Throughout the sixteenth and seventeenth centuries, the majority of states around the world were monarchies. This form of government, in which political power is lodged with an individual (a king, sultan, shah, emperor, etc.) could be found in the Americas, where the Aztecs and Incas established strong monarchies; in Africa, where numerous kingships and principalities were spread throughout the continent; and in Asia, which included some of the greatest empires such as Qing China, the Ottoman empire, and Safavid Iran. Many monarchies retained the feudal basis of political balance between king and nobles but also experienced important changes throughout the sixteenth and seventeenth centuries. Thus, in Japan the emperor's authority was all but relegated to the great lords (daimyos) and the shogun, and their factional struggles eventually

produced a prolonged political upheaval that, in conjunction with a rising merchant class and an encounter with Europe, made pure feudalism no longer sustainable in the country. By the 1600s Japan emerged as a highly centralized state where daimyos still existed and were given social prestige but where true power resided with the shogun and an efficient bureaucracy, while the emperor was consigned to a nominal leadership position. In China the Manchu (Qing) dynasty, which came to power in the mid-seventeenth century, produced a successful combination of the Manchu military capability and the Chinese administrative expertise. Emperor Kangzuo (1662–1722) contributed to greater government centralization, and by the eighteenth century China probably was the most centralized and closely regulated state in the world.

The most profound change in the nature of monarchical rule occurred in Europe. In the early 1500s Europe consisted of hundreds of independent or semi-independent states. Over the next 200 years, however, there was a rapid consolidation of power in some of these states. In France, King Louis XIII (assisted by Cardinal Armand Jean du Plessis de Richelieu) and King Louis XIV steadily expanded their authority at the expense of the nobility. They stopped convening the Estates General, France's medieval assembly, and passed laws as they saw fit, suppressing noble dissent while expanding a bureaucracy drawn from the gentry and merchant classes. By the late seventeenth century the French monarchy exercised such great power that the political system it created became known as an absolute monarchy. "Absolutism" is the term by which we describe the political organization that results from

Royal authority was not subject to any challenge or check by judicial, legislative, or electoral bodies. A succinct summary of these principles is Louis XIV's famous expression "I am the state."

the theory that absolute sovereignty vests in a monarch. Royal authority was not subject to any challenge or check by judicial, legislative, or electoral bodies. A succinct summary of these principles is Louis XIV's famous expression "I am the state." Yet although this power was theoretically absolute, in practice it was exercised by royal officials who were given consider-

able latitude in interpreting and carrying out royal orders.

However, absolutism was not the only path of monarchical development; there were several alternatives. Some monarchies were theocracies, a form of government in which a deity is recognized as the state's supreme ruler, with the state governed by persons who are regarded as divinely guided. Louis XIV's belief that he personified the state probably could have been easily shared by the Aztec rulers in Mexico who served as a representative of the gods on earth. The Inca empire in South America was ruled by the Inca, who was considered semidivine. Yet the Aztec and Inca states were not as highly centralized or integrated as France and consisted of dozens of conquered polities whose governments were often left unchanged if they recognized Aztec and Inca authority and met their obligations. In Iran, Shah Ismail, who founded the Safavid dynasty in 1502, was a devout Shia who claimed divinity and descent from the prophet Muhammed himself, notwithstanding his Turkic background. Although the later Safavid rulers downplayed such assertions of divinity, they still emphasized their ancestry. In Europe, John Calvin's reforms

in Geneva led to the creation of a theocratic government that tightly controlled the society. In Oceania, the islands of Polynesia and Hawaii developed hierarchical societies led by chiefs whose power and status were inherited, but unlike European or Asian monarchs, downplayed the importance of bloodlines in favor of historical ties to the land.

Even in Europe, absolutism was far from a universal trend. The European Age of Discovery resulted in a revolution in commerce and trade in turn resulted in the rise of a strong merchant class whose interests often clashed with those of the existing political elite. Thus England and Holland, the most successful commercial powers, were pulled in the opposite direction from the prevailing trend toward absolutism, moving toward limited monarchy. In seventeenth-century England, with its long parliamentary tradition, a growing political struggle erupted between the Crown and Parliament. This along with the religious turbulence of the Reformation, led to a brutal Civil War (1642–1649), the execution of the king, and an interruption in monarchical rule. This period produced important theoretical discussions on the nature of the state. Shocked by the chaos and destruction of the civil war, Thomas Hobbes, in his influential work *Leviathan* (1651), championed the idea of a strong government capable of protecting its subjects. Hobbes argued that the royal power came not from a divine right but rather from a “social contract,” a mythical unwritten agreement among the people to established government. Early humans lived in a state of nature, Hobbes argued, when the government did not exist and each person was free to do exactly as he or she pleased without any legal restrictions but also without the protection that laws afford. Uncontrolled by law and government, Hobbes famously wrote in Chapter III of *Leviathan*, “the life of man [was] solitary, poor, nasty, brutish, and short. . . . They [were] in that condition which is called war; and such a war, as is of every man against every man.” To put an end to such lawlessness, people entered into a social contract whereby they gave up their individual liberties for the political order and stability delivered by a king. Hobbes believed in the absolute power of the monarch, declaring that “nothing the sovereign representative can do to a subject, on what pretence soever, can properly be called injustice or injury.”

Hobbes’s ideas inspired another English philosopher, John Locke, to write his famous *Second Treatise on Government* in 1690. By then England had experienced a major transformation. Although monarchy was restored in 1660, continued conflict between the monarch and Parliament led to another confrontation during 1688–1689. In what became known as the Glorious Revolution, Parliament asserted power over the monarchy, largely through control of the purse strings. Locke’s philosophy reflected this political change. He shared Hobbes’s belief in a “social contract” but also contended that the king’s authority should be limited by this very contract that carried the people’s consent to be ruled. If the government misused or overreached its authority, then the people had the right to withdraw their consent and terminate the agreement. In his treatises on government Locke explicitly stated the people’s right of revolution to oppose unjust rule and overthrow authority.

In the eighteenth century, European states developed diverse political forms. Some states tried to imitate Enlightenment principles. Centralized states with strong armies and bureaucracies successfully

developed in Prussia and Russia, while the Habsburg dynasty made similar (but less efficacious) efforts in the Austrian empire. Austrian absolutism was based on asserting the dominance of Habsburg authority over national affairs while allowing for some level of autonomy in local affairs, particularly in Bohemia and Hungary. Other states, such as Sweden and Poland, joined the English in rejecting an absolutist government. Thus, by the seventeenth century Poland's monarchy was elective and subject to the Assembly of Nobility (Sejm), which exercised the liberum veto (in which any deputy could put an end to the current legislative session and nullify all legislation passed). A few states even rejected monarchy altogether in favor of a republican form of government. In its early years the Republic of Venice was ruled autocratically by a doge, but his powers were later greatly curtailed by several councils (the Maggior Consiglio, the Council of Ten, and the Signoria) that represented the aristocratic families of this city-state and functioned as an oligarchic government. By the early seventeenth century the Dutch Republic emerged as a decentralized confederation of seven provinces that broke away from Spain. Each state had its own government led by a stadtholder but was also governed directly by the States General (Staten-Generaal), the federal government, that had a limited authority. A similar form of government existed in Switzerland, a confederation of 13 cantons each with its own government and traditions.

Religion played a very important role in the political life of a state. Medieval European theologians often compared a state to a divinely created organism where the king was the head, the aristocracy the arms bearing weapons, and the rest of people, the commoners, the torso. A more comprehensive metaphor, which took into consideration Divine power, became known as “the Great Chain of Being,” which presented the universe in terms of a great hierarchy (God, angels, humans, animals, etc.) and sanctioned stratification of human society with the king at the top, followed by aristocrats and other social groups. This belief reinforced the notions of paternalism (that those at the upper end of the chain had a responsibility to look after those below them) and of deference (the homage that the lower orders were supposed to offer to those above them

on the chain). In China, Confucianism promoted a set of key virtues such as *ren* (compassion, benevolence), *li* (courtesy and civility), and *xiao* (devotion and deference) that facilitated and protected the hierarchical society in which every member knew his or her place and responsibilities. Steeped in the values of the past, Confucianism ostensibly discouraged innovation and commercial enterprise, although such enterprises often did quite well in China.

Chinese civil officials, who had to pass rigid examinations on Confucianism, might openly disdain the greed and materialism associated with trade and commerce, but in the interest of the state's well-being bureaucrats and merchants often formed beneficial alliances. In fact, a great number of people holding bureaucratic positions were born into commercial families. In the Islamic world the very titles

In China, Confucianism promoted a set of key virtues such as ren (compassion, benevolence), li (courtesy and civility), and xiao (devotion and deference) that facilitated and protected the hierarchical society in which every member knew his or her place and responsibilities.

of Muslim rulers were directly connected to religion. A caliph (khalifah rasūl Allāh, or “successor of the Messenger of God,”) was perceived as prophet Muhammed’s successor in political and administrative functions, while a sultan, according to the Quran, was a person of moral or spiritual authority, although the term later came to carry political power as well. By 1517 after conquering Syria, Egypt, and Arabia, the Ottoman rulers combined both titles in their persona and held them until the early twentieth century. The Ottoman sultans, although possessing unlimited authority in theory, had to conduct themselves in accordance with the Quran, Islamic religious law (Sharia), and Islamic customs.

In the New World, religion was at the very heart of state formation. The Aztecs established their state on an island in Lake Texcoco, as it fulfilled the teaching of their most important god Huitzilopochtli that at the location of their new home they would find an eagle perched on a cactus and devouring a snake. Religion also provided a mechanism of social control due to a cosmic mission that Aztec religious beliefs propagated. The Aztecs believed that the sun, the source of all life, must be sustained by a divine elixir found only in beating human hearts. For this purpose human sacrifice had to be offered regularly, since a failure to do so would doom the world to destruction. These views allowed the Aztec elite to maintain commoners in subservience, justify state expansion, and terrorize conquered peoples. In the Inca state the authority of the supreme leader (Inca) was based on his divine descent from the sun god Inti. Worshipped in his lifetime, the ruler was embalmed after his death and revered as a god. On special occasions all the Inca mummies would be assembled to ask them for advice on affairs of state.

While all religions ostensibly seek peace and tranquility, dogma is oftentimes used to justify political intrigue and conquest. Thus, the relationship between the Ottoman empire and Iran was mired in a deep-seated hostility between the Sunnis and Shiites that sustained prolonged conflicts between two states. In the Iberian Peninsula religion played a key role in the centuries-long Reconquista, the struggle of local Christian kingdoms against Muslims who also conducted war in God’s name (jihad). Similarly, religious differences played a role in European attempts to organize Crusades against the Ottoman empire in the mid-fifteenth century. At the same time, religion became one of the key factors in the European Age of Expansion since, aside from economic motives and personal glory, the Spanish, Portuguese, and other explorers were clearly driven by the desire to spread the message of Christ to the newly discovered territories. This, however, oftentimes posed major challenges to Europeans. In Japan, for example, the spread of Christianity caused the Tokugawa shoguns to restrict European activities, eventually expelling all Europeans (except the Dutch) and closing down Japan’s borders. Yet in India, the Mughal rulers became known for their tolerant approach to religious issues and actively sought to incorporate non-Muslim (primarily Hindu) groups into the framework of the empire. The Mughals repealed laws that imposed special taxes on non-Muslims and encouraged interfaith marriages. Emperor Akbar exemplified this policy as he opened the *ibadat khana* (“house of worship”) where representatives of various religions (including Christian missionaries) were invited to engage in spirited debate and discussion.

Such tolerance, though, was lacking in Europe. Jews were forbidden to own land in many countries, and their involvement in trade and commerce often drew abuses from their Christian competitors. Jewish communities were oftentimes the target of violent attacks and were occasionally entirely expelled from the country. Thus, in 1492 tens of thousands of Jews were expelled from Spain, followed by expulsion in Portugal during 1496–1497, Brandenburg in 1510, Muscovite Rus in 1547, Genoa in 1567, the Austrian empire in 1670, the French West Indies in 1683, and Sweden in 1685. In 1516 Venice established the first ghetto in Europe, where Jews were forced to live and could not leave after sunset. The start of the Reformation in the early sixteenth century only further complicated religious and political dynamics in Europe. In

Thus, in 1492 tens of thousands of Jews were expelled from Spain, followed by expulsion in Portugal during 1496–1497, Brandenburg in 1510, Muscovite Rus in 1547, Genoa in 1567, the Austrian empire in 1670, the French West Indies in 1683, and Sweden in 1685.

1500 Europe was largely Catholic, with only parts of southeastern Europe practicing Eastern Orthodox Christianity. By the mid-seventeenth century, as a result of ideas of Martin Luther, Ulrich Zwingli, Jean Calvin, and other reformers, the religious map of Europe completely changed, and Scandinavia, most of Germany, Switzerland, Scotland, and England embraced Protestantism. The Reformation had a profound impact on political life in Europe.

Oftentimes religion was difficult to distinguish from politics. England's break with the Catholic Church had much to do with both Protestant influence and King Henry VIII's desire to ensure the stability of his dynasty. Subsequent religious strife in England led to an acute political crisis as the country plunged into civil war in the mid-seventeenth century. Most of Europe experienced political turmoil caused by religious foment. In France this religious conflict is most famously represented by the St. Bartholomew's Day Massacre (1572), a purge that claimed thousands of Protestant lives and began a 17-year-long conflict. Yet another manifestation of the rift between Catholics and Protestants was the Thirty Years' War that devastated Germany, killing millions and fragmenting the region.

Despite differences in forms of government or religion, states oftentimes shared a common goal of conquest and dominance. Rivalry for prestige, territory, or natural resources produced an unprecedented spate of wars, revolts, and revolutions throughout the world between 1450 and 1750. Analyzing these events, several important patterns can be discerned. The Italian Wars that involved France, Spain, the Holy Roman Empire, and the Italian states in the early sixteenth century not only contributed to the spread of Italian Renaissance culture throughout Europe but also influenced the theory and practice of conquest. This conflict further accelerated Europe's "military revolution," which in turn laid the foundation for the modern bureaucratic state. The skills, experience, and technology that Europeans gained in Italy were later successfully utilized in conquering lands around the world. In the New World the depletion of local populations due to the introduction of new diseases as well as Spanish and Portuguese mistreatment and

enslavement resulted in the importation of African slaves to work the cash crop economies developing in the Caribbean colonies. The shift from indigenous to African coerced labor had profound consequences for the subsequent history of the New World.

This period also marked a gradual global shift in wealth and power from Asia to Europe, which established some of the largest and most powerful states in the world. Southern and eastern Asia, the home of Mughal India, Safavid Iran, and the Ottoman empire, was one of the wealthiest regions in the world in the early sixteenth century. Yet by the mid-eighteenth century European trading companies shifted international trade routes and created a global trading network that they continued to dominate. The focus of the global economy soon shifted away from the Indian Ocean, greatly affecting Asian powers. The European discovery and conquest of the New World was followed by the rise of the Atlantic triangular trade that involved slaves from Africa and colonial products from the Americas. The mercantile system that Europeans developed defined the relations between newly colonized regions, which supplied raw material, and mother countries, which fabricated finished goods for consumption in the colonies and elsewhere, adding to profits. Thus, by the seventeenth century Islamic states, which previously enjoyed the status of dominant commercial powers, were eclipsed by the much smaller states of England and Holland that controlled the main commercial lanes in the Atlantic and Indian oceans.

■ Introduction: Control, Coercion, and Crime in State and Empire

The power of a state, by its very nature, is based on control and coercion. Scholars agree that one of the essential characteristics of the state is that it claims “the monopoly of the legitimate use of physical force in the enforcement of its order,” as Max Weber stated in *The Theory of Social and Economic Organization*, or “the principal means of coercion within a given territory,” as Charles Tilly argued in *The Formation of National States in Western Europe*. In Europe as a whole, state control and coercion mechanisms followed parallel paths of evolution since the Middle Ages. At first, European monarchs pursued a patrimonial system—extracting whatever capital they needed as tribute or rent from lands and populations under their control. They provided a legal framework and justice while their coercion apparatus, as a

rule, consisted of various vassals or retainers that provided service within certain contractual limits. However, starting in the fifteenth century, the sovereigns became increasingly dependent on a brokerage system, in which they relied on independent capitalists for loans, tax collection, or the management of various enterprises. These greater financial means allowed many rulers to change their system of coercion, which increasingly featured mercenary forces that were either hired directly or provided by contractors on certain conditions. This system eventually facilitated the development of nation-states, where rulers, while centralizing their authority, subordinated fiscal mechanisms directly to the state and restricted independent contractors. The sovereigns established national armies and navies (through conscripting their own

citizenries) that were controlled and maintained by the state's expanding administrative and financial structures. As was true elsewhere, states were also involved in maintaining religious conformity, although gradually their power became more tenuous after the Protestant Revolution.

Outside Europe, some states established stricter control and coercion systems. The Aztec and Inca civilizations developed in distinctive, rather isolated environments, yet both civilizations were based on political hierarchies that effectively used control and coercion mechanisms. The Aztec state was probably much more coercive than the Incas, turning a human sacrifice into a divine obligation which it implemented with remarkable efficiency. The Aztecs subjugated other Amerindian cultures to harsh domination which caused many of them to welcome the Spanish arrival. The Inca state developed a peculiar coercion policy to secure the loyalty of the conquered peoples. Once defeated, a conquered population was subjected to a process known as *mitima* or resettlement and integration. The people were resettled to various corners of the empire where, within a generation or two, they were gradually assimilated.

In China, the Ming dynasty's code gave it authority over all aspects of life, even specifying that the occupations of all Chinese subjects were hereditary and could not be changed at will, yet the Ming governmental structure was never of sufficient strength to exert effective control, even if it so desired, if subjects were intent on resistance. The Chinese system was subject to the pervasive *lijia* system of collective societal organization, by means of which the society was able to maintain order and control through all levels. The *lijia* system (which located every person in a hierarchy of command reaching as high as the emperor) was based on the traditional *baojia* organization (neighborhood mutual responsibility structure), which organized the society for more effective control. During the Ming (1368–1644) and its successor Qing (1644–1911) dynasties, each household was integrated into this system. A variety of lineage or village authorities maintained order, supervised tax collection, and oversaw the moral conduct of the community. Chinese authorities attempted to control the movement within the

country. Commoners exiting or entering a village were required to notify authorities while anyone traveling farther than 100 li (30 miles; 50 kilometers) were supposed to obtain a special pass (*yin*). In theory, commerce was subject to supervision; overseas commerce, trade in salt and tea, and mining of precious metals were either forbidden or tightly regulated. To legally trade, Chinese merchants had to be licensed under the legal threat of banishment or even death; enforcement, however, was uneven, and there was a thriving coastal trade. The Ming dynasty attempted strict control over religion as well, closing all temples and monasteries except one in each county (*zhou*) and requiring government approval for construction of new temples. The activity of monks was supervised by specially established bureaus locally and by the Ministry of Rites on a national level. In Japan, the long civil strife ended in the establishment of the Tokugawa *bakuban* system that centralized government and created a strict hierarchical society to preempt social chaos and rebellion. The basis of Tokugawa power was control of the land which the shogun granted to *daimyo* or feudal lords for governances.

The Islamic world was no exception to the prevailing types of control and coercion. The Ottoman state was based on a patrimonial system in which it controlled the collection and distribution of resources and claimed monopoly over the means of coercion, but also granted rural revenues in exchange for services rendered to the state. Combining practices from the ancient Near East, the Byzantine empire and the precepts of Islam, the Ottomans developed a rather efficient control mechanism that, through a combination of direct and indirect rule, maintained order over a vast empire. A key institution of central control—the Janissaries—was maintained through the coercive *devşirme* levy of Christian children (primarily from the Balkans) that allowed the state to maintain political control. Yet, starting in the sixteenth century, the Ottoman state experienced a fiscal crisis, worsened by inflationary trends, rebellions, and increasing military expenditures, that weakened its control over parts of its territory as well as its economy. The Ottoman sultan pursued various policies to meet these challenges, including

contracting out to private groups (families, kinship groups) some aspects of control mechanism, for example, the recruitment and provisioning of fighting forces to support main Ottoman armies. Such compromises, however, eventually contributed to the weakening of the Ottoman central authority.

Safavid Iran, although exhibiting some characteristics of the early modern Western state (e.g., use of gunpowder technology, concept of absolutist monarchy supported by institutionalized religion), remained in essence a premodern state based on the patrimonial system. Iran's constrained production capacity and weak economy meant that the Safavid rulers, while claiming absolute power, were in reality quite limited in their authority and oftentimes sought tribute more than stable control over a population or region. Financial constraints prevented the Safavids from establishing a large bureaucracy that could have ensured tighter control over the country. Furthermore, the Safavid central control remained, except for the reign of Shah Abbas I (1587–1629), rather tenuous in parts of the states, and particularly on the periphery, where the Qizilbash tribes remained the mainstay of the Safavid military and administrative order. Abbas' reforms, which aimed at remedying this predicament, included expansion of the ghulam corps of military slaves as the key institution of central control and coercion.

—*Alexander Mikaberidze*

Slave Power Empires

Powerful slave trading empires were mostly located along Africa's coastline. The emergence of coastal states as powerful slave trading empires was accidental. Long before the arrival of Portuguese explorers and traders, African pastoralists living in central and western Sudan engaged slaves to increase the cultivation of crops and to provide domestic service. In West Africa, slaves represented a large section of the population and slaves could attain positions of importance in the royal household or could serve as advisers to African rulers. By the time the first European appeared in West Africa, slavery had become fully integrated into local society but its definition varied across the multiple societies. Unlike

European societies, which tended to view slaves as property that could be bought and sold, African societies practiced socially and politically more complex slavery, usually absorbing slaves through manumission, marriage, or service.

Some African states possessed vast numbers of slaves and depended on slavery for their economic output. In the central Sudan region, Kutumbi, the leader of the Kano in the first half of the seventeenth century, developed his well-known reputation as a slaver by capturing thousands of slaves. Kutumbi settled several hundred of his own slaves near Kano. Relying on captives, one of Kutumbi's generals built his headquarters and sent another 2,000 slaves to Kano. In some cases, slaves were used by African rulers as militia for defensive purposes. Farther east, captives were settled around the capital of the Sultanate of Sennar by Badi II as farmers; these slaves also provided military support in case of foreign invasion. These slave-farmers provided little military opposition to the well-armed and well-trained armies of the other states in the Sudan. Although they were not of great value militarily, Badi II valued the slaves for their agricultural production that would feed his armies. During the eighteenth century, the sultans of Dar Fur employed slaves on agricultural settlements adjacent to their capital. In addition to producing food, slaves could be employed to produce other manufactured goods. Some Dar Fur aristocrats could have as many as 600 slaves working within their domain.

West and East African states developed an extensive trade in ivory and slaves. Slaves were purchased by Muslim merchants and sent to India, Arabia, and the Persian Gulf. Muslim merchants were sometimes supported by African leaders—for example, Mirambo of Nyamwezi—in opening trade routes, establishing states, and returning large quantities of ivory and slaves. Mirambo began by hiring Ngoni mercenaries and later adding war captives, escaped slaves, and deserters, forming them into an armed militia. Mirambo and his army successfully operated during the age of the slave trade, and his mercenary armies were linked with other chiefs to form a single state in southern Tanzania, eastern Zambia, and Malawi.

With the arrival of Europeans, particularly the Portuguese, the internal slave trade changed

THE KINGDOM OF DAHOMEY

Located in one of the poorer regions of the West African coastal region, Dahomey emerged as a powerful principality under the leadership of the Aja dynasty in the early seventeenth century. During the reigns of King Wegbaja (1650–1685) and King Akaba II (1685–1708), Dahomey embarked on wars of expansion and conquered areas south and southeast of Abomey, followed by expansion into Allada and Ouidah to control trade with Europeans in the early eighteenth century. The Dahomey rulers established a strong monarchy based on the principles of primogeniture and divine worship of kingship. Yet, Dahomean kings were not absolute monarchs and consulted frequently with the council of ministers, as well as prominent merchants and military leaders.

In the process known as Dahomeanization, the Dahomean kings turned conquered states into fully integrated provinces within the kingdom, where no separate leadership or laws were recognized. Instead, the conquered regions were controlled by a Dahomean governor who was assisted by village heads in the execution of duties. In order to achieve homogenization of laws, customs, and institutions in conquered states, the laws and customs of Dahomey took precedence. The state also introduced standardized weights and measures and traded in a standard currency of cowry

shells. Efficient administration developed around a system of messengers known as the half-heads, who were stationed at relay stations throughout the kingdom, maintaining communications between the central government and the provinces. An annual census counted all livestock and the state collected income tax, custom duties, and road tolls. Dahomey's rulers used an increasing number of slaves for agricultural production which supported the urban population. Dahomey also played a leading role in the transatlantic slave trade, gathering vast numbers of slaves at special coastal stations, where they were sold to European slave ships that visited every month or so. In fact, slave exports became a state monopoly and profits of slave dealers were taxed by the state.

The tax and slave trade revenues, together with guns and ammunition gained in trade with Europeans, became the foundation for Dahomey's power. Its kings maintained a well-trained army, which increased in size and efficiency until the mid-nineteenth century, and the Dahomey conducted wars of expansion along the southeast and southwest borders. Rivalry between Dahomey and Oyo in the eighteenth century was instrumental in generating a large number of captives who were sold into the Atlantic slave trade.

—Alexander Mikaberidze

as the external slave trade developed. Local African laws required the payment of a fine for legal transgressions, but as the external demand for slaves increased, African rulers imprisoned convicted criminals who would later be sold as slaves to Europeans. Although the sources of slaves varied, many of the slaves sold on the coast were prisoners, the result of local wars fought to establish new African states or to expand states in the African interior.

The Muslim Fulbe of Futa Jalon created a new state by waging war against neighbors, creating an abundant supply of war captives who could be sold into slavery. The rulers of Oyo, Dahomey, and Asante engaged in political wars of expansion, becoming powerful African states. As a rule, African leaders infrequently sold their own subjects into slavery, but they also knew the handsome price that European slavers offered

could make them quite wealthy. Local territorial conflicts produced a steady and abundant supply of human commodities.

Located west of where the Niger River empties into the Atlantic Ocean, the Bight of Benin became one of the major slave-exporting regions of West Africa. Beginning slowly, the export of slaves grew to enormous heights surpassing the Portuguese-controlled region around Luanda, earning the Bight of Benin the moniker the Slave Coast. The export slave trade became the first state monopoly controlled by the Oyo. Increased hostile conflict, which led to many new war captives, accounts for the major upsurge in the enslavement of numerous people from the interior of Africa. Several wars instigated by the Yoruba kingdom of Oyo against the coastal towns of Ardrah, Whydah, Porto Novo, and Lagos resulted in increased numbers of people indentured for

the slave trade. Also located inland, the Dahomey raided farther north, obtaining captives for sale in the coastal trade, and challenged Oyo and the coastal towns for dominance of the trade with the Europeans. Oyo eventually forced Dahomey to pay tribute, but hostilities between Oyo, Dahomey, and the coastal towns continued producing combat prisoners who served as human commodities fueling the slave export business.

Examining various regions of Africa suggests that African rulers conducted trade based on local conditions. The Slave Coast experienced minimal European contact depending on the closeness of European ships to the coastal towns and the activities of Muslim traders. African leaders dealt with Muslim traders who brought slaves and other trade goods from the interior to the coast through an interregional trading system. Developments within the Slave Coast trading system hinged on political centralization. The rulers of the Oyo and Dahomey kingdoms created stronger centralized governments because of their dealings with other nations to the north and the necessity to maintain control over their own territory. African rulers understood that maintaining the military readiness necessary to acquire new captives and to defend itself required an organization and a bureaucracy to regulate European trade.

Traveling west from the Slave Coast, seventeenth- and eighteenth-century traders would land in the towns of Accra, Winneba, Cape Coast, or Elmina along an area that Europeans called the "Gold Coast." In terms of the slave trade, the Gold Coast never reached the significance of the Slave Coast, but Europeans still landed there because of the area's reputation as a source of gold. Although not a major source of slaves, political strife among the Akan resulted in a supply of captives. The Asante rulers and their armies successfully subdued several smaller states and took control of the Gold Coast. In the second half of the eighteenth century, the Akan wars resulted in approximately 150,000 slaves. Taken as a whole, the Gold Coast mirrored the Slave Coast. Few European traders traveled inland, and African leaders and the newly formed centralized African states restricted European trade to a few coastal towns. To the east of the Niger Delta, in the Bight of

Biafra, another area emerged where African leaders participated in the slave trade. Because of its mangrove swamps, the coast along the Bight of Biafra developed later than the Gold Coast or Slave Coast as a source of slaves. By the late 1670s, the towns of Aboh, Bonny, and Elem Kalabari were noted depots of the slave trade, but the major economic expansion in the Bight of Biafra occurred later in the eighteenth century. The coastline proved to be inhospitable even to the heartiest slavers, leading to a sparse presence of Europeans. The minimal Muslim influence demonstrates the difficulty in conducting trade on the swampy coast. Because of the harsh terrain, the strong centralized governments that emerged within the areas around the Slave Coast and Gold Coast rarely materialized along the Bight of Biafra. As a result, the slave trade developed a different character. Instead of prolonged warfare, including punitive reprisals, raids, and tribute payments, local village leaders organized and conducted slave raids and kidnapping expeditions against neighboring villages, bringing captives to the coast in canoes down the winding delta tributaries. Although the Bight of Biafra never reached the same level of slave exports in the eighteenth century as the Slave Coast, it has the distinction of surpassing all other West African regions.

The Fulbe of Futa Jalon and along the coast in the Gulf of Guinea, the centralized monarchies of the Asante, Dahomey, and Oyo all accumulated large amounts of state-owned slaves through repeated, extended wars. Because these confrontations between kingdoms vying for control of the slave trade often decided the economic and political stability of the region, African leaders often chose to execute their enemies and turncoats as part of their victory. Although African leaders transported large amounts of captives to the coast, African rulers curtailed the removal of people within their own kingdoms. The Asante on the Gold Coast ended the mass removal of local people to the coast, and once the Oyo became dominant along the Bight of Benin, they prevented the export of slaves from within their own borders. Once the Oyo empire lost its strong grip, exports of Yoruba slaves increased.

Slavery and the slave trade needed the support and protection of the centralized government to

survive, expand, and produce immediate short-term wealth. The political authorities ensured property rights for slave owners and traders. Governments protected the transportation of slaves and the slave markets, making escape or rescue difficult. Government regulation and involvement in the trade, however, did not translate into ownership of all slaves. For example, the kings of Asante and Dahomey exercised rights over all slaves within their kingdoms, but they did not own all slaves. Government interest in the capture, transportation, and sale of slaves resulted in the establishment of laws and regulations governing the trade. Regulations required the payment of a variety of fees, duties, and other charges. African states imposed monetary charges on traders for anchorage, wood, and water. Depending on the level of control African rulers exercised over commercial activities, traders may have been required to pay for brokers, interpreters, and other services. Beginning with the Portuguese, traders built several forts along the coast of Africa, with Elmina on the Gold Coast being the most notable. These forts served as trading depots during the slave trade while others doubled as protection against interlopers. None of these forts would have lasted without the permission of the local African ruler or community. The occupier of the fort paid taxes and obtained provisions from the surrounding villages. These forts were useful in making available the interior trading routes and contact with slavers and merchants.

Moving from codifying slavery and the slave trade into law, it was a short step to making slavery a social institution that could be passed to future generations as part of African social tradition. Many African states grew and prospered from their capability to control the slave trade. With government involvement, the law, a new social tradition, and the increased external demand for slaves, African rulers appeared more than willing to exchange their greatest asset, young men and women, for money.

African Political Organization

By the mid-fifteenth century African states spanned almost the entire continent, with the kingdoms of Mali in west Africa and Songhai, Kanem-Bornu, and Hausaland in central Africa, while Ethiopia and the famous Swahili city-states prospered along the eastern coastline of Africa. Sub-Saharan Africa was a vibrant region that included both large and powerful kingdoms and smaller but flourishing societies united by family or kinship ties.

In eastern Africa, the Christian kingdom of Ethiopia enjoyed a revival under the ruling Solomonid dynasty, which controlled a vast territory from the Red Sea port city of Massawa in the north (in present-day Eritrea) south to Shoa in the central highlands. In the fourteenth century Ethiopia embarked on a campaign of expansion, which brought it into a prolonged conflict with the neighboring Muslim states. The Solomonid rulers initially enjoyed a series of military successes that ensured Christian dominance in the region. This period of political and economic stability led to Ethiopia's religious and literary revitalization as well. The political situation, however, changed in the early sixteenth century. Ahmad ibn Ibrahim (otherwise known as Gran, "the left-handed"), the ruler of Adal, declared a religious war on Ethiopia and launched a series of campaigns that between 1529 and 1543 spread death and destruction in Ethiopia. Continued military setbacks forced King Galawdewos (r. 1540–1559) to seek help in Europe, especially from the Portuguese. With the help of a small but well-armed Portuguese contingent,

the Ethiopians drove the Muslims out of the central highlands and later conducted successful campaigns throughout the 1550s, 1560s, and 1570s. Aside from immediate devastation, this long conflict also changed the dynamics in the southern highlands of Ethiopia, where the Oromo (also known as the Galla) tribes of pastoralists from the grasslands of the south began to infiltrate and to settle. The Oromo arrival altered the demographic picture of highland Ethiopia and later profoundly affected Ethiopian politics. Continued warfare devastated many Ethiopian churches and destroyed literary and artistic treasures. Close contacts with Portugal inevitably led to Jesuit missionary activity, which the Ethiopian Church perceived as a threat, and theological disputes between the Jesuits and the Ethiopian clergy created a protracted religious and political schism in the kingdom. Although revived under the leadership of the *yetégé* ("empress") Mentewwab, one of the most remarkable women rulers of this age, the Ethiopian kingdom fell into the long Era of the Judges (1769–1855) when emperors changed in rapid succession as a result of bitter struggles between nobles, the most powerful of them being the Oromo nobles who dominated the Ethiopian kingdom until the 1850s.

Farther south in coastal eastern Africa existed the Swahili city-states that developed a reputation for commercial prosperity. The cities of Mogadishu, Mombasa, Kilwa, and Sofala maintained trade contacts throughout the Indian Ocean, the Middle East, and Africa and reached their peak of development in the fourteenth through the fifteenth centuries. Fiercely competitive, the cities vied for political and commercial hegemony, in the process creating a unique cultural legacy. They embraced religious syncretism as represented in festivals and competitive celebrations that combined local and Islamic traditions. The Swahili ritual calendar combined the Persian solar calendar for local rituals, farming, and navigation with the Arabic lunar calendar for religious celebrations. The arrival of the Portuguese fleet led by Vasco da Gama in 1498 marked a turning point in the Swahili cities' history. The Portuguese soon embarked on building their maritime empire in the Indian Ocean, and the Swahili city-states were ill-prepared to defend themselves. But the European occupation of the

city-states proved to be fleeting, as thousands of residents left their cities such as occurred in the city of Kilwa, which the Portuguese abandoned in 1512. Furthermore, after their triumph over a Muslim and Indian coalition in a naval battle at Diu in 1509, the Portuguese accorded low priority to the east African coast and concentrated their efforts on India and Arabia. The initial Portuguese withdrawal from eastern Africa created a political vacuum, and many Swahili city-states were plunged into periods of turmoil as their overseas commerce collapsed. Some towns, such as Kilwa and Mombasa, turned inward and developed commercial ties with the hinterlands. By the end of the sixteenth century the Portuguese dominance in the Indian Ocean declined, following the kingdom's disastrous invasion of Morocco in 1578 and the Spanish takeover of Portugal in 1580.

As Portuguese garrisons in Africa were drawn down, at least for the time being, the Swahili cities saw the arrival of a new power. Following their conquest of Egypt during 1516–1519, the Ottoman Turks had gradually expanded their influence to Arabia and the Red Sea. Their struggle against the Portuguese posed them as potential allies to Swahili towns, which now supported Turkish efforts in the Indian Ocean. Throughout the 1580s the appearance of Ottoman forces caused a series of revolts of Swahili towns, which the Portuguese, again aware of the importance of eastern Africa, now subdued. Having reestablished their dominance on the coast, the Portuguese made Mombasa the center of their new and reinforced presence, which endured for almost four decades. By the mid-seventeenth century the Portuguese faced a new threat when the Omani Arabs became determined to drive them out of the northern Indian Ocean. In 1661 an Omani raid sacked Mombasa, ending Portuguese power on the coast north of Mozambique. While individual Swahili towns remained largely independent, Omani suzerainty, which persisted for the next 200 years, led to an upsurge in trade as well as a profound Arab influence in religion, law, commerce, architecture, dress, and vocabulary.

Southern Africa experienced a history that was distinct from western and eastern Africa. Until the arrival of the Portuguese in the fifteenth

century, southern Africa developed outside of direct influence of the Mediterranean cultures and the Islamic world. Southern Africa's political and religious life centered around several polities that developed well before 1450. The most important of these was the kingdom of Zimbabwe, which rose to prominence in the thirteenth century and flourished until the fifteenth century. Its capital, Great Zimbabwe, extended over 60 acres (24 hectares) and included a formidable edifice, known as the Great Enclosure, consisting of a fortified enclosure with walls as high as 36 feet (11 meters). The state's wealth rested on the area's rich gold-bearing belt, resulting in a profitable gold trade with the eastern coast. In the mid-fifteenth century the kingdom of Zimbabwe rapidly declined, perhaps because of soil exhaustion and overpopulation. By the time the Portuguese reached eastern Africa, Great Zimbabwe and most of the kingdom had been abandoned. Instead two new states emerged, the kingdom of Mutapa, stretching between the Zambezi and Limpopo rivers in the north, and the kingdom of Butua in the south. Both states developed in the tradition of Zimbabwe until they were taken over by the Rozwi empire.

Western Africa had long served as an important trade region where caravans from northern Africa and the Middle East traded with local states. The region was initially dominated by the kingdoms of Ghana and Mali, but by the fifteenth century several new states emerged. Thus, the state of Wolof gained its independence from Mali in the north, while Kantora remained under Malian influence in the south. These states usually had a well-defined government hierarchy, with a king, often elected by nobility, presiding over the state. But not all sub-Saharan peoples had formed states, and many lived in stateless societies led by family or clan elders. These societies were agrarian in nature, and the cultivation of land was the primary occupation of its members. Families helped each other in clearing land from surrounding forest, cultivating it, and gathering the harvest. In Senegambia, a region between the Senegal and Gambia rivers, millet, sorghum, and yams were the staple food, supplemented with plantains, beans, fish, and small game, while in the south along the coast of Guinea rice played an important part in daily life. As Robert W. July,

a prominent scholar of precolonial Africa noted, "life was simple, government was largely limited to the settlement of disputes by family heads or elders, the basic economy scarcely more than the production and consumption of food, social life centered on the ceremony accompanying birth, death and family alliance."

In the fifteenth century a new powerful state, the kingdom of Benin, emerged in present-day Nigeria. Ruled by an *oba* (divine king), the Benin kingdom came to prominence under the leadership of Oba Ewuare (r. ca. 1440–1473), who overcame tribal and village chiefs (*uzama*) to centralize his authority and considerably expanded his realm's borders. His successors Ozolua (r. 1481–1504) and Esigie (r. 1504–1517) continued his policies. At its height in the sixteenth century, the kingdom of Benin controlled a vast territory between the Niger River in the east and Yoruba country in the west. In 1485 the Portuguese reached this region, and the ensuing profitable trade in spices (primarily pepper) and slaves further strengthened Benin. Its capital, Benin City, became one of the great urban centers in Africa, a city of 25 miles (40 kilometers) in circumference protected by walls and intersected by numerous streets and avenues. The city was divided into two sections, the larger for the town's residents and the smaller for the elite and royalty. As trade flourished so did the arts, and the Benin craftsmen refined their skills with copper and brass, producing elaborate pieces of art. These Benin bronzes, magnificent in their craftsmanship, vividly conveyed the oba's power and authority as well as recorded tradition and folk tales. Sadly, nothing remains today of this glorious city; in 1897 a British expeditionary force led by Admiral Sir Harry Rawson conquered and destroyed the city and much of its famous buildings and treasured art.

To the north of Benin lay Songhai, a successor state of Ghana and Mali. Songhai was the last of the three great empires of the western Sudan. The Songhai state was founded under the leadership of Sonni Ali (r. 1464–1492) when Songhai authority extended to almost the entire basin of the Niger River, including the famous Timbuktu. Sonni Ali showed himself to be a talented military and political leader who divided his empire into provinces, established a navy (led by

a commander known as the *bi-koy*), and promoted trade. Upon his death a power struggle between his successors ensued, which ended in the victory of Muhammad Ture, a devout Muslim of Soninke origin who soon took the title *askiya* ("great leader"). Askiya Muhammad I Ture (r. 1493–1538) completed the expansionist and administrative policies of his predecessor Sonni Ali. He conducted wide-ranging campaigns that brought new regions under Songhai authority. A convert to Islam, he made a hajj (pilgrimage) to Mecca and used Islam to unite his far-flung empire. After his successful wars of expansion, Ture reorganized the administrative system set up by Sonni Ali. Ture divided the empire into four viceroyalties, each under a viceroy or governor, usually chosen from the royal family or a trusted servant. He established a council of ministers and replaced local Songhai officials with more efficient Arab ones. Under the leadership of Ture, Songhai enjoyed economic prosperity, and visitors remarked on its abundant food supplies and vibrant trade. European and north African commodities (clothes, perfumes, copperware, glass, etc.) were in high demand and were delivered by European and Muslim merchants. Following their expulsion from Spain in 1492, a large number of Jews came to Songhai, where they quickly became involved in trade. Ture revived Timbuktu as an important educational and Islamic center, and its reputation soon drew many Muslim scholars and clerics for educational pursuits as well as for trade. In 1513 Leo Africanus visited the town and was struck by "a great store of doctors, judges, priests, and other learned men that are bountifully maintained at the King's court." After a 35-year reign, the aged Ture, known as Askiya the Great to later generations, was deposed by his children in 1528. His successors failed to live up to his legacy, and the Songhai state quickly declined amid internal dissent and political turmoil before being finally destroyed by the invasion of the Moroccan sultan al-Mansur in 1591. In the aftermath, the once-great empire split into numerous small kingdoms.

To the east of Songhai the kingdom of Kanem-Bornu prospered. By the fifteenth century the state of Kanem, founded by the Kanuri, a mixture of people from south of the Sahara and

Berbers from the north, already had existed for some 600 years. However, in the mid-1400s the weakened Kanem was absorbed by the rising power of the Bornu state, leading to the establishment of the powerful kingdom of Kanem-Bornu. Throughout the sixteenth century the kingdom rapidly expanded under a succession of able *mais* ("kings"), the greatest of whom was Idris Alawma (r. ca. 1571–1603). His victorious campaigns greatly expanded the kingdom's territory, while shrewd domestic policies resulted in a centralized state administration and a profitable trade. A devout Muslim, Idris Alawma built mosques at his capital city of N'gazargamu and introduced Islamic law in place of African customary laws. However, as often happens, Alawma's successors proved to be less capable, and the kingdom gradually declined and was later absorbed into the French West African empire.

The Ottomans as a Gunpowder Empire

Hodgson's "gunpowder empires" theory is an important contribution but prone to oversimplistic interpretations. The Ottoman sultanate's successful introduction of firearms into the military system was instrumental in its rise to empire. However, the real reason behind its success lies not with firearms but with skillful military organization backed by an efficient financial-administrative system that proved more adaptable to conditions than its rivals. In opposition to earlier theories, recent academic research is increasingly showing that the successful introduction of firearms became possible because of

➤ CONSTANTINOPLE IN 1453

Gunpowder weapons, as well as the strategic and tactical skills of the 21-year-old sultan Mehmed II (r. 1444–1446 and 1451–1481), were equally important factors in the successful siege and conquest of Constantinople in 1453.

Mehmed II the Conqueror (Fatih) carefully secured his empire's borders by diplomatic and military means. By taking into account the experiences of four failed sieges of his ancestors, he mobilized all the resources of the state. He raised units and collected volunteers from all corners of the Ottoman world who were not only Turk but also included Bulgarian, Serb, Albanian, Greek, and even some Latin warriors. In order to achieve an effective blockade, he constructed a naval fleet and a coastal fortress, which would be located on the opposite shore of the existing one in Asia, whose cannons cut off Constantinople from the Black Sea. Above all, a strong siege train including huge bombards was assembled, using European and local expertise.

After two long years of preparation, the siege began on April 5, 1453, with artillery fire and continued with mining and occasional frontal attacks. The exceedingly small Byzantine army, which was vastly outnumbered, was reinforced by the city's greatly reduced civilian population, several thousand foreign mercenaries, and some volunteers and successfully withstood these early attacks by using an elaborate defensive system. The Ottoman navy failed to breach the boom closing the entrance of the Golden Horn and was unable to enforce its blockade. Four large Christian supply ships ran the blockade after a day-long naval skirmish on April 20.

Sultan Mehmed overcame some of the tactical difficulties presented by the city's fortifications, which had repulsed numerous attacks over the past 1,100 years, by ingenious methods, such as moving ships across land into the protected harbor known as the Golden Horn and designing cannons to hit specific targets. Even though the Byzantine defenses and morale were increasingly weakened (particularly after seeing Ottoman vessels in the Golden Horn), the Ottoman side also suffered significant problems. The conservative governing elite under the leadership of Chandarli Halil Pasha was increasingly unhappy and vocal with each passing day. They were certain about the impossibility of the fall of Constantinople and were uneasy about the increasing risk of a European

The Siege of Constantinople in 1453, from Le Voyage d'Outremer by Bertrandon de la Broquiere, fifteenth century. (Library of Congress)

army of relief coming to the aid of the city. Mehmed, however, convinced respected religious figures and ulema to support the siege and encouraged his soldiers by talking about divine omens and signs. He also made use of the financial expectations and greed of the soldiers by promising three days of looting and plunder.

All of his available units were organized into three waves and positioned mainly against three breaches, which had finally been created in the walls. The final assault started before dawn on May 29, 1453. The first wave consisted of mercenaries and volunteers who bore the brunt of the attack and were virtually annihilated but at the same time wore out the defense further. Azabs (Anatolian infantry) attacked as a second wave and nearly scaled the walls. At this critical moment Mehmed ordered the final wave of Janissaries to attack. The defense collapsed after a last stand, and Ottoman soldiers poured into the city.

—Mesut Uyar

centralized administration. Consequently, the financial and administrative demands of firearms encouraged the centralization process.

The Ottoman empire inherited Central Asian steppe-nomadic, Islamic, and Byzantine traditions. By blending this heritage into a unique form, the Ottomans were able to overcome their rivals and occupy the eastern Balkans and western Anatolia without using firearms. But when increasingly faced with firearms in the western Balkans, they were quick to introduce and make use of them at the beginning of the fifteenth century. Slowly but steadily, special units were raised and equipped with firearms, and cannons became indispensable parts of siege trains. The Ottomans proved very adaptable, borrowing not only new technology but also the tactics and techniques to use this technology effectively. After suffering difficulties against Hungarian war carts (*wagenburgen*) armed with light cannon and arquebuses, the Ottomans copied these weapons and employed them successfully against these same Hungarians in less than five years. Even a special military corps was founded to use war carts.

Obviously, firearms proved to be an important element in the Ottoman military victories after the fall of Constantinople in 1453. Ottoman siege trains captured many fortresses, including modern ones in the Balkans and Hungary. The Ottomans also defeated their Asian rivals in a series of pitched battles—Otlukbeli (1473), Chaldiran (1514), Mercidabik (1516), and Ridaniye (1517)—though not always easily. But when analyzed closely, each of these sieges and battles shows clearly that the main factor behind the victories was an efficient military organization with its complex logistics. The enormous task of transportation of guns to the battlefield became possible with a centralized administration and its mobilization of resources. However, firearms were not numerous in the combat units. Due to the drawbacks of arquebuses, which were slow, inaccurate, and often faulty, the Ottomans preferred to keep traditional composite bows as the main weapon in their timarait, or feudal, cavalry and also as an alternative weapon within the Janissary corps until the end of the sixteenth century.

The growth and development of a bureaucracy and increased scrutiny of untapped

sources for taxation and mobilization went hand in hand with the ever-increasing size of the army. In order to supply an army conducting continuous campaigns in the east and the west, the Ottomans built state-owned cannon foundries and munitions and gunpowder factories in both the big cities and frontier centers. Additionally, a complex administrative and socioeconomic system was devised in order to produce the necessary amounts of modern weapons and good-quality gunpowder. At the same time, great care was given to following the developments taking place in Europe, and special measures were regularly taken to acquire new firearms technology. During the sixteenth and seventeenth centuries, the Ottoman military-industrial complex remained the largest in Europe and West Asia.

The Ottoman empire also played a crucial role in the diffusion of firearms and firearm technology, though not always intentionally. Persia acquired firearms from the Ottomans, initially as war booty but mainly with the help of deserters and mercenaries and also through illicit trade. Ottoman-trained mercenary musketeers became sought-after elements not only in Persia but also in Central Asia, Afghanistan, and India. These so-called Rumis ("Romans," so-named because Ottoman Anatolia had been the land of the eastern Roman empire) altered local power balances by providing services to the different conflicting sides.

After the uncontrolled diffusion of firearms to the east, the Ottoman sultans began to send parties of guns, technicians, and soldiers to various Islamic states. Even though none of these parties was big, they were still effective. Ottoman aid improved the capabilities of the Uzbeks against Persia and the Aceh sultanate in Sumatra against Portugal. Official Ottoman military advisory teams and profit-oriented mercenaries played an even more important role in North Africa. Their aid to Morocco proved to be a crucial factor in Morocco resisting a Portuguese invasion. More importantly, Ottoman corsairs and mercenaries independently conquered Algeria and Tripoli (Libya) by making use of their expertise of firearms. These conquests were incorporated into the empire later on. In some cases, however, Ottoman military help turned out to be counterproductive, as was true in the case of

Morocco. With Ottoman technology and know-how, Moroccans were able to defeat the Portuguese and extend their influence deep into the Sahara. But they also successfully blocked Ottoman expansion into the far-western regions of North Africa.

In addition to these Islamic lands, some non-Muslim countries, such as China, received Ottoman firearms through indirect means.

The diffusion of firearms and firearm-bearing mercenaries also affected Ottoman society. The increased reliance on mercenaries and militia created a volatile atmosphere inside the empire. Raised from essentially urban unemployed youths armed with firearms and organized into free companies, mercenaries were willing to work for whoever could afford to pay them. They were also well accustomed to banditry and extortion of money from the civilian public. Even large punitive expeditions did not solve the problem. Internal brigandage affiliated with mercenaries continued on until the nineteenth century.

Being a traditional agrarian empire, the Ottoman empire also increasingly suffered problems coping with West European military technology after the Industrial Revolution. The Ottoman economy was no match for the Western nations' enormous production capacities. Thus, the empire was unable to protect itself against the destructive effects of Western economic imperialism. The effects of continuous wars on both fronts—Asia to the east and Europe/North Africa to the west—which exhausted financial reserves and destroyed local economies, must also be taken into account.

Contrary to common belief, the vested interests of the governing elite and established army corps did not create additional barriers to the reception of new technology, but they did hinder the acceptance of new military drills, tactics, and techniques.

Regardless, the conservative formation of the military worked well for several centuries but not after the end of the eighteenth century. Even before then, however, the Ottoman military had difficulty creating its own new weapons and adapting effective tactics and techniques to use whatever firearms they had. Quite simply, the Ottomans were never able to found academic and technical institutions to deal with

military education, training, research, and development. The lack of academically trained officers, printing presses, and military literature effectively blocked the dissemination of military knowledge and discussion. This deficiency was also instrumental in maintaining traditional on-the-job training as the backbone of the Ottoman military education. The first printing press was opened in 1727 and closed after 16 years without making any important contribution to the military. The first military manual/drill book was printed a century later in 1828. After many failures, the first modern military engineering school was founded in 1795 with limited enrollment, and a modern military academy for infantry and cavalry corps was founded in 1834.

Crime, Policing, Legal Systems, and Punishment in Early Modern India

Political and social developments in early modern India led to a diverse, overlapping, and at times innovative legal system that was often tolerant in its ability to adjudicate among various religious groups and within diverse jurisdictions. Though *dharmasastra*, or dharma, existed as a system of Hindu written law, it did not serve to unify the Indian legal system and deferred to varying and changing local customs. The Mughals, who were Muslim rulers, applied Sharia, or orthodox Muslim law, though Hindus were allowed to appeal to Hindu law. The close

ASIA IN 1700

of the early modern period revealed a powerful and profitable British East India Company eventually recognizing Muslim and Hindu law.

Hindu judicial administration relied on local customs and on strong public belief in justice, all under the authority of the monarch. Social control and change relied on this sense rather than on an emphasis on statute, case precedence, or a professional class of advocates. Defendants and plaintiffs could be represented by close friends or relatives in minor cases. Increasingly competence in dharma seemed to play a role and even representation was required, but the relationship to the party concerned was paramount. In civil matters Hindus were allowed their own tribunals. In Hindu law when there was a conflict

between Hindu commentaries and local custom, the latter usually prevailed. Indigenous minority Christian populations were often assimilated into Hindu society and as such were afforded the protection of Hindu law.

In Islam sovereignty belonged to Allah, and it was the duty of the king to rule in his name and to see that his decrees were followed. Here royal courts had jurisdiction over Muslim commercial, civil, and family concerns. However Sharia was qualified by royal decrees, customs, or, at times, corruption. Rulers such as Akbar (r. 1556–1605), Jahangir (r. 1605–1627), and Shah Jahan (r. 1628–1658) considered administration as part of their devotion to God, whether punishing offenses against religion, focusing on

daily administration of government, or in ensuring new reforms. Mughal rulers, on the whole, afforded legal toleration to Hindus.

The pinnacle of Muslim legal toleration and justice was under Akbar, who achieved a solid administration over northern and central India. His empire was divided into 12 provinces, each under a governor. These were subdivided into districts. Cities had their own governors who oversaw various boards. They also had their own police force, though the countryside was secured by district military commanders. Though each had their procedural traditions, much depended upon the will of the sultan, who had power of remission or enhancement of sentences. Sharia was interpreted by the highly respected scholars called *ulama*. The *kazi*, or judges, enforced this law, though appeals could be made to the emperor. At the village level, Hindus often appealed to the *dharmasastra* in court cases. Judgment was issued either through the opinions of a Brahmin knowledgeable in the law or through the *panchayat*, which was a council of five ruling a Hindu village. If witnesses for the plaintiff were competent and consistent, testimony for the defendant usually held little weight. Unless there was an appeal to the emperor, the decision was final. Usual punishments varied in range and included fines, whipping, public humiliation, banishment, and even death. Mughal India contained very few prisons.

However, under Aurangzeb (r. 1658–1707) toleration was abandoned. He appointed censors in large cities to enforce Sharia. Proper prayers were to be performed, Hindus were to build or repair their temples, and their religious fairs were outlawed. Aurangzeb even tried to abolish gaming and illicit sex. When crowds gathered to protest his rule of ruthless power and terror, he responded by ordering imperial elephants to crush them.

Premodern India had witnessed an increased level of laws governing associations. These included laws for merchants, traders, soldiers, religious specialists, agriculturalists, and even castes. This even allowed for progressive change in that intermediate-level associations were involved in the creation and administration of law.

Though the East India Company was certainly not interested in progressive change and

in fact engaged in increasing brutality, it did eventually affirm Hindu and Muslim law. Charters of 1600 and 1609 gave the company authority to make laws and to enforce and police them within the domain of English factories. Officially by 1753 Indians could be granted exemptions in the mayor's courts and have their cases decided based on their own religious laws. However, in 1757 the company gained military power in Bengal under the brutal and brash leadership of Robert Clive (1725–1774). He left the *nawab* with no money and little power to oversee the criminal justice system and the military administration. Police, soldiers, and legal officials were left unpaid, and lawlessness, corruption, and even starvation of the native population ensued. Clive left for England in disgrace and there committed suicide. The scholarly and methodical Warren Hastings (1732–1818) superseded him as governor, and Hastings's Mufassal Regulation of 1772 officially affirmed Hindu and Islamic legal toleration. However, another body of law, now English Common Law, would add to the diversity (and complexity) of laws governing the subcontinent.

Exerting Imperial Control under the Ming (1368–1644) and Qing (1644–1911) Dynasties

The general drift of imperial control during the Ming and Qing dynasties was toward an increased level of autocracy and a strong

centralization of power in the hands of the emperor. The position of the educated classes who filled the role of bureaucracy was on the whole lowered, while government management of society in general increased. Religious organizations and individuals were also more closely monitored than they had been in the past. The Qing government also supervised and censored all written texts in the empire. Nevertheless, the degree to which government controlled the state or the people was far less than that experienced by people in the twentieth century.

During the preceding Yuan dynasty (1279–1368), the Mongol rulers had turned the Chinese world upside down by their thorough disdain of the scholarly class. They had cancelled the examination system and lowered the legal status of Confucian scholars. The Yuan emperor was theoretically all-powerful and in practice maintained a great distance between himself and his ministers. One particular matter was the practice of having offending ministers beaten, which continued under the Ming. Although the system was partially revised during the latter half of the dynasty, with the reinstitution of the exam system in 1313, the Yuan set the tone for the imperial period.

The founder of the Ming, Zhu Yuanzhang (1328–1398), had a long reign and was important in establishing the Ming state and government. He established a thoroughly reworked law code, the Ming Code. During the 1370s and 1380s he also wrote many books of rules for the empire, its people, and his own family.

One way in which Zhu increased the power of the position of emperor was in the permanent abolition of the office of prime minister. Another was in his periodic purges of the bureaucracy, which created a distinct element of fear among the officials who would serve in the government.

Zhu also implemented rules to control both the Buddhists and Daoists and to limit their numbers. These laws provided that both would ultimately be under civil authority, and in many cases those who became monks or nuns needed to pass exams set by the state. Nevertheless, in practice, state control over religion was limited.

The third emperor of the Ming, Zhu Di (r. 1402–1424), who usurped the throne from his

ON COMBATING THE MONGOL THREAT— MING-QING RESPONSES

Although the emperors of the Ming and Qing dynasties took the Mongol threat very seriously, their approaches differed. The Mongols, who were composed of many tribes, differed in their attitudes toward the Ming dynasty. After the fall of the Yuan dynasty, some of the Mongol tribes accepted the Ming and became part of their tributary system. Other Mongol tribes, however, particularly those in the far north, never recognized the Ming. The Yongle emperor (Zhu Di) responded to the threat posed by the Oirat Mongols with a series of five campaigns between 1410 and 1424. These campaigns did not resolve the Mongol threat. The Zhengtong emperor (Zhu Qizhen) also resorted to a military campaign. However, he was not only defeated but was also captured at the Battle of Tumu in 1450. For the remainder of the Ming dynasty, the Mongols remained a threat. This threat was resolved by the Manchu rulers of the Qing dynasty, who combined a policy of military suppression and religious activity. Kangxi defeated Galdan, leader of the Zunghars (a Western Mongol tribe), in 1696, and Qianlong's armies completely destroyed them by 1760. The Manchus also held important influence with the Dalai Lama, who was highly esteemed by the Mongols. This combination was successful in resolving the Mongol threat.

—Ihor Pidhainy

nephew, was also responsible for many of the practices during the Ming dynasty. He increased opportunities for scholars to serve and contribute at court but at the same time had them carefully observed. He established the Eastern Depot, a secret police force that was run by the eunuchs (who also played a more important role under him). In addition, he also expanded the powers of the Embroidered Uniform Guard, a unit of military men who served as military police. The Eastern Depot and the Embroidered Uniform Guard worked in tandem in many extralegal ways.

These powers were increased during the opening of the Qing dynasty. The Qing ruling house was Manchu, a northeast Asian people who had managed to take over after the Ming fell. The Manchus spoke a different language,

EXPANSION OF QING CHINA, 1683–1760

practiced different religions, and had different customs and habits than the Han Chinese, and in establishing their rule the Manchus were obliged to ensure the loyalty of their Han citizens. The rulers carefully controlled and watched for any seditious elements.

They did this by instituting a number of measures. They reorganized the government so that each department was headed by a Manchu, and they created a double bureaucracy so that for each position there was one Manchu and one Han member. The rulers also carefully monitored all literature for any signs of political disloyalty or ethnic slurs. Of the several purges

of literature, the most infamous was under the Qianlong emperor during 1772–1788, a period in which numerous works were destroyed. Many scholars were executed, and their families were made slaves. The early Qing emperors also instituted various methods of spying upon their government officials whether they were Han or Manchu. This secret service is well documented in state archives.

The Qing rulers increased the role that government played in the lives of common people. The rulers required all men (except for Buddhist and Daoist monks) to dress and wear their hair in the Manchu manner. Those who went against

the requirement were severely punished. The rulers were unsuccessful, however, in imposing a ban on foot binding among the Han women.

The general drift of the latter two dynasties was one of further involvement and control of both the bureaucrats and the local people. Nevertheless, the reach of the government through its officials was miniscule compared to society today.

Sengoku Jidai—The Warring States Era in Japan, 1467–1600

The Sengoku period, or Warring States Era, in Japanese history was a time of great social upheaval, political instability, and frequent military conflict between rival contending factions within Japan. The age was one of the darkest and most troubled in Japanese history as fighting raged throughout the country. The third Ashikaga shogun, Yoshimitsu (1358–1408), had asserted shogunal power over most of Japan, but after his death the shogunate declined so much that for more than a century it was almost completely powerless as a central government. (The Shogun was the dominant military figure in the country whose army controlled the government and who ruled through regional military figures known as daimyo or lords, who in turn ruled their domains in the name of the shogun.) The domains of many daimyo were ravished by the internecine battles among vassals or frequent peasant uprisings.

Historians interpret the Warring States Era as a period both significant and filled with ambiguities. In some scholars' interpretations, this era of conflict and instability extends from the onset of the Onin War (1467–1477) until 1568, when Oda Nobunaga (1534–1582) marched his

army into Kyoto to impose national hegemony upon regional warlords. Other historians emphasize its beginnings in 1490, when Hosokawa Masamoto (1466–1507), the *kanrei* (shogunal deputy) seized actual control of the Muromachi shogunate. Still others trace the beginnings of instability to 1491, when Hojo Soun (1432–1519), formerly a minor samurai, conquered Izu Province and began his rise in the Kanto (now Tokyo) region and end the period in the very early 1600s with the rise of the Tokugawa shogunate (1600–1867).

The term *gekokujo* (the overthrow of those on top by those below) is often employed to

➤ BUSHIDO

The term “Bushido” (“the way of the warrior”) originated in Japan during the Edo period (1600–1867) and describes the ethical code of the ruling samurai (warrior) class. Bushido implies not only a high degree of martial zeal and skill with weapons but also absolute loyalty to one's lord, a strong sense of personal honor, devotion to duty, and the courage and conviction to sacrifice one's life in battle.

Bushido developed in Japan's medieval period when bands of warriors serving their lords became engaged in frequent battles. The relationship involved the warriors deriving favors from their lord in exchange for their service. Modern historian Watsuji Tetsuro wrote that the core of the medieval lord-vassal relationship was a “total, unconditional self-renunciation on the part of the follower to his lord.” On the other hand, historian Ienaga Saburo argued that the relationship was basically economic and contractual: the follower's loyalty could be held only as long as the lord was able to bestow favors. Other historians argue that the truth lies somewhere in the middle: some samurai gave unconditional service to their lords, while for others it was conditional.

The famous kabuki and bunraku puppet play *Choshingura* dramatized the Bushido philosophy. The production recounts a 1701 incident in which the 46 samurai of a lord, forced to commit suicide due to his violent response to an insult by a higher official, assassinate the official and then commit mass suicide.

—*Daniel A. Métraux*

characterize this era. A rapid decline in the power of shogunal leadership and the impotency of the imperial court in Kyoto had left a power vacuum that was filled by the rise of regional military figures. Because none of these local leaders was able to overpower his rivals, there was constant fighting and an endless series of alliances and counteralliances until Oda Nobunaga was able to overpower his rivals in 1582.

Ironically, the turbulent political atmosphere of the Sengoku period stimulated considerable economic growth, technological innovation, commercial expansion, and urbanization. Sengoku daimyo worked to empower and enrich their own domains by carrying out flood control and land reclamation projects. Rice harvests and cotton cultivation grew substantially, as did the production of other raw materials for the handicraft industries. These developments led in turn to the rapid growth of the cotton industry and the widespread production of domestic yarn and cloth. The mining industry also grew rapidly, furthering the development of gold, silver, iron, and copper and leading to the expansion of foundries and smiths. There was also a major expansion of commerce with the opening of many new stores and the improvement of roads and boat transportation.

Increased trade even stimulated the formation and growth of commercial cities and market towns such as Sakai, Hyogo (now Kobe), Kuwana, and Hakata. Kyoto revived as a cultural and industrial center. During the latter part of the Sengoku period, castle towns such as Inuyama grew up around the fortresses of prominent daimyo and became important commercial and political centers.

The Sengoku period also saw the popular diffusion of culture that formerly had been the domain of the elite nobility and clergy of Nara and Kyoto. Zen priests and *rengashi* (popular linked-verse poets invited to the provinces by Sengoku daimyo) played a major role in the popularization of cultural activities. Wealthy merchants patronized the tea ceremony, the Noh theater, new forms of music, and other traditional arts. Books aimed at the general public found many customers. Zen Buddhism flourished, and Christianity gained a foothold as the first Europeans began visiting Japan in the early to mid-1500s.

The political instability of the period ended with the conquests of Oda Nobunaga, whose rise from obscurity to power was typical of *gekokujo*. Oda built an army that dominated central Japan from 1568 through his assassination in 1582. His death provided the opportunity for Toyotomi Hideyoshi (ca. 1536–1598), one of Oda's own generals who had risen through the ranks from foot soldier (*ashigaru*), to seize power and consolidate his control over much of the rest of Japan. Hideyoshi's death in turn led to the rise of a daimyo Tokugawa Ieyasu (1543–1616), whose powerful peasant army, equipped with modern guns and cannon, defeated rival forces at the Battle of Sekigahara in 1600. Ieyasu then established the Tokugawa shogunate, which ruled a highly unified Japan throughout the Edo period (1600–1867).

The Tokugawa Shogunate

The military hierarchy that formed the Tokugawa shogunate was based on alliances and loyalties. These associations were solidified in 1600 in the Battle of Sekigahara. In this pivotal clash, Tokugawa Ieyasu defeated his opposition, formed at least nominally of those loyal to his predecessor, Toyotomi Hideyoshi. After 100 years of civil war, one of the key issues for the victorious new regime was to ensure continuity and stability. In order to negate any threat to

THE FORTY-SEVEN RONIN

The vendetta of the forty-seven ronin, also widely known as Chushingura ("Treasury of Loyal Retainers") or the Akô Incident (the retainers' home domain), is one of the most widely dramatized events in Japanese history. From the first version as a kabuki play in 1703, just two weeks after the vendetta had concluded, the story has been retold in theater, fiction, television, and film. The actions of the ronin are said to exemplify samurai traditions, especially the value of loyalty.

In 1701, the fifth Tokugawa shogun Tsunayoshi (1646–1709) assigned responsibility for escorting an imperial envoy from Kyoto to two shogunal officials. Directly responsible was Asano Takumi no Kami Naganori (1667–1701), while the older Kira Kozunosuke Yoshinaka (1641–1702) was to super-

vise Asano. Tensions erupted between the two, supposedly because Asano did not give sufficient deference or provide monetary gifts to Kira. One day, taunted by Kira, Asano committed the grave crime of drawing his sword within Edo Castle. Even though Kira was only wounded, for his offense Asano was sentenced to commit *seppuku* (ritual suicide). His retainers went underground for almost two years. On a snowy night in December 1702, led by Ôishi Kuranosuke (Yoshio) (1659–1703), they attacked and decapitated Kira. They then took his head to Senkakuji Temple to lay on the grave of Asano and awaited arrest. In recognition of their devotion, they were allowed to commit seppuku rather than be executed like common criminals.

—Martha Chaiklin

the new government, those warlords who had opposed Ieyasu at Sekigahara or who were simply too powerful were relocated to the edges of the country and designated *tozama*, or outsider daimyo, that is, great lords who had supported Tokugawa Ieyasu. Those daimyo who were perceived as loyal (*fudai*) and those of their collateral houses (*shinpan*) were placed in strategically important locations. Any daimyo who did not comply with this arrangement had their lands confiscated, often absorbed into the Tokugawa domain, which increased significantly in size in the early years. For the most part the highest positions in the shogunate did not go to *tozama* daimyo but instead were reserved for those considered more loyal.

A set of laws aimed specifically at the warrior class (*Buke shobatto*), which was first issued in 1615 and revised several times thereafter, demanded clean and frugal living, adherence to the demands of status, and loyalty to the shogunate; prohibited the formation of alliances; and commanded service to the shogunate.

As soon as he received the title of shogun in 1603, Ieyasu similarly asserted authority over the imperial court in Kyoto, potentially a challenge to his legitimacy, by issuing a number of regulations directed toward controlling the court. Ieyasu also consolidated his rule through an ideology that placed heaven, rather than

Hanging scroll of Tokugawa Ieyasu, seventeenth century. Tokugawa-Ieyasu inherited the remains of his father's domain and became the most powerful lord in Japan. He founded the Tokugawa, or Edo, shogunate, which effectively ruled Japan from 1600 to the Meiji Restoration of 1868. (Topham/The Image Works)

the emperor, as the ultimate source of authority. Thus, by extension those who were disloyal would receive punishment from heaven. By the mid-seventeenth century Neo-Confucianism was also being promoted as official orthodoxy by the adviser to the first four shoguns, Hayashi Razan (1583–1657), and his family. Because Neo-Confucianism was essentially secular and focused on empirical understanding of the physical world and yet emphasized loyalty and harmony based in a natural, immutable order, it could integrate disparate elements into the service of the shogun.

Ieyasu established a Magistrate of Shrines and Temples (*jisha bugyō*) because armed Buddhist temples had been a serious problem in the past, and he wanted to ensure that they did not present a political challenge. Nevertheless, Buddhism as well as Shinto played important roles in the regime. Shinto had already been fused with Neo-Confucian ideas by some Muromachi period (1333–1573) thinkers, and later in life Hayashi Razan also adopted some of these syncretic ideas. Tokugawa Ieyasu claimed to be the “Sun God of the East.” This appellation gave legitimacy to his regime and at the same time was another way to remove power from the Imperial House, which claimed descent from the sun goddess Amaterasu. On its part Buddhism, although reduced in influence from former times, was still patronized by all ranks of society. Consequently, as part of the shogunal campaign against Christianity, everyone was required to register affiliation with a Buddhist temple.

When the process of unification had begun under Oda Nobunaga around 1560, there had been no aversion to the outside world. It was in fact the successful adoption of firearms, first brought by the Portuguese, that aided Nobunaga in his quest to conquer. The first step toward insularism came in 1587 when Nobunaga’s successor, Toyotomi Hideyoshi, suddenly ordered all Christian missionaries out of the country and placed bans on Christianity. Until that time official policy toward the Jesuit Mission, which had been established in Japan in 1549 by Francis Xavier, had ranged from welcoming to neutral. The Jesuits were shocked and puzzled by the decree, and even today the motivations for the sudden policy shift are unclear. Although

the immediate effects were small and only three missionaries left, the decree marks the beginning of anti-Christian political policy. The Jesuits responded by keeping a low profile, but in 1592 Spanish Franciscans arrived in Nagasaki in contravention of the Papal Bull of 1493, which had divided the world between Portugal and Spain. These newly arrived missionaries openly flouted shogunal rules. The catalyst for action, however, was the *San Felipe* Incident of 1596, which highlighted the friction between the Jesuits and the Franciscans and exacerbated Japanese suspicions about Christianity. The captain of the *San Felipe*, angered that his cargo had been confiscated and hoping to influence its return, warned that the missionaries only preceded conquistadors and crystallized Japanese fears of its political menace. The following year twenty six Christians, the so-called Nagasaki Martyrs, were executed for violating the bans.

After Hideyoshi’s death in 1598, Ieyasu was initially tolerant of Christians because their presence was seen as a corollary to having foreign trade. Foreign relations were seen as another way to legitimate his rule. Relations with Korea, which had been rocky since the attacks on Korea under Hideyoshi in 1592 and 1597, were regularized in 1606, and an ambassador was received the following year. Limited trade, conducted through Tsushima, occurred throughout the Tokugawa period.

However, many of the daimyo remained loyal to Hideyoshi’s son Hideyori, and thus Christianity took on internal political implications because many southern tozama daimyo had converted to Christianity. When Ieyasu (although no longer shogun but still in power) mounted an assault on Hideyori in 1614, he combined it with renewed persecution of Christianity. Missionaries were expelled, and followers were punished. Some priests remained but went underground, while others were smuggled in. Evidence obtained from the papers on a ship found that smuggling missionaries convinced the Japanese authorities that the Spaniards would never abandon missionary activities, and thus all Spanish ships were barred from coming to Japan. The economic necessity of trade through Macao prevented the same from happening to the Portuguese, but Japanese attitudes

THE SAKOKU EDICTS

Harbor of Nagasaki showing Deshima, about 1800. (Library of Congress)

Although Japan was once connected to the Asian continent and contact with the world beyond its borders has been frequent, Japan has fostered a sense of isolation known as *shimaguni* (“island nation”) mentality. In the early modern period, isolation was legally enforced through the *sakoku* (“closed country”) edicts.

Based to some extent on earlier bans on Christianity and trade regulation that had confined foreign trade to Hirado and Nagasaki, the third Tokugawa shogun, Iemitsu (r. 1623–1651), issued a

series of five edicts. The first, in 1633, tightened restrictions on Christianity and trade, forbidding Japanese who had lived overseas from returning and restricting the movements of Japanese ships. The second edict the following year merely reiterated the first, but the third in 1635 also forbade any Japanese from leaving. The edict of 1636 required that the Portuguese move out of the city of Nagasaki and onto a small fan-shaped artificial island called Deshima, and any children of Iberian parentage were required to leave the country. The final edict in 1639 expelled the Portuguese and required the children of other nationalities to leave. In 1641 the Dutch were required to move to Deshima, and all foreign trade except Korea (Tsushima) and the Kingdom of Ryukyu (through Satsuma) was conducted in Nagasaki.

The intent and effect of these measures is still widely debated, and most scholars no longer think of Japan as having been totally closed. The origin of the term “*sakoku*” is indicative of this because it was coined by the western-oriented Rangaku (“Dutch learning”) scholar Shizuki Tadao (1760–1806) in his 1801 translation of an essay by the German natural scientist and physician Engelbert Kaempfer (1651–1716), who had spent two years in Japan and advocated the notion that it was in Japan’s best interest to remain “shut up.”

—Martha Chaiklin

had shifted. A series of regulations known as *sakoku*, or “closed country” edicts, restricted access to Japan for natives and foreigners alike. The Shimabara Rebellion, a Christian-led uprising in 1637, gave the Japanese authorities reason to expel the Portuguese. Japanese foreign trade was more or less limited to the Netherlands and China and was conducted in Nagasaki until commercial treaties were enacted in the late 1850s.

Over this time period, interaction with foreigners was restricted. The Dutch, although restricted to trade from the small artificial island known as Deshima, were given daimyo status and were required to visit the shogun every year. Chinese trade, established after the founding of the Qing dynasty in 1644, surged until restrictions were put in place in the early eighteenth century and then leveled off. The Ryuku

Islands (present-day Okinawa Islands), which maintained their own king, sent embassies on occasion, but the Ryukyus had been officially annexed by the daimyo of Satsuma (located on the Japanese island of Kyushu) in 1609. Once these policies were in place they gained the legitimacy of tradition, whether that had been the original intent or not.

As the Tokugawa period progressed, insular thinking resulted in the development of a school of intellectuals known as *kokugakusha*, or nativists, who believed that Japan had been polluted by contact with the outside world, especially Chinese, Buddhist, and Confucian influences. They sought to purify Japan from these outside influences. These ideas would ironically be significant in bringing about the end of the shogunate in 1868, by virtue of the belief that

true loyalty should be directed at the emperor rather than the shogun.

Vietnam—The Nguyen Lords

At the beginning of the fifteenth century there was a dramatic change in Vietnamese history as the Ming dynasty occupied Dai Ngu/Viet and ruled it as Ming China's 14th province from 1407. Le Loi's decade-long rebellion ended Ming Chinese rule in 1428, and his coronation inaugurated Vietnam's longest-ruling dynasty. Yet less than 100 years after its founding, the Le dynasty was riddled with trouble and owed its nominal restoration to two increasingly powerful but competing families: the northern-based Trinh, who essentially held the Le emperors hostage, and the Nguyen, who were carving out an ever-expanding autonomous domain in the south.

The rise of the Nguyen and the Trinh families, both with origins in Thanh Hoa province (in present-day central North Vietnam), began with the usurpation of the fledgling Le throne by Mac Dang Dung (r. 1527–1530). Nguyen Kim (1467–1545), a notable court official related to the Le dynasty through marriage, decided to help restore Le rule; in this he was aided by Trinh Kiem (d. 1570), his ambitious son-in-law. By the time of Nguyen Kim's death in 1545 (allegedly poisoned by the Mac), the Le dynasty had set up court at Thanh Hoa, but it was the Trinh family who had begun to establish themselves as the power behind the throne.

Kim's son Nguyen Hoang (1524–1613) nevertheless continued to cooperate fully in the campaigns to restore the Le but was acutely aware of his increasingly powerful brother-in-law who was suspected of killing his older brother. In 1558 Nguyen Hoang thus requested the position of governor of two southern frontier provinces, Thuan Hoa and Quang Nam, with the aim of being at a safe distance from Trinh Kiem with an opportunity to build up an alternative power base. After Trinh Tung (r. 1570–1623) and Nguyen Hoang had dislodged the Mac from Thang Long (present-day Hanoi) in 1592, the Le dynasty was formally restored, but effective power remained with the Trinh. In recognition of his services, Trinh Tung was even given the title of king (*vuong* in Sino-Vietnamese; *chua* in Vietnamese), a privilege that his descendants, the Trinh Lords (Chua Trinh), conveniently retained.

In the face of such ambitions, and having satisfied his filial duties to restore the Le, Nguyen Hoang retreated to his southern fiefdom. From their capital near present-day Hue he and his descendants, the Nguyen Lords, would consolidate and enlarge their power base. The southward thrust of the Nguyen armies integrated the remaining Cham territories and also wrested most of the Mekong Delta from Cambodia, in the process creating a new southern Vietnamese space that extended to the Gulf of Siam. Although the Nguyen Lords still recognized the nominal overlordship of the Le emperors, the Trinh Lords in the north (Dang Ngoai) could not accept that their former allies were essentially carving out a new autonomous kingdom, called Dang Trong, in the south. In 1627 the bitter rivalry between the two families came to a head when Nguyen Phuc Nguyen (r. 1613–1635) opposed Trinh attempts at domestic interference and demands for tribute. During the next half century the Trinh and Nguyen fought over their differences, until a truce recognizing the status quo power balance was eventually reached in 1672.

The Nguyen Lords used the ensuing 100 years of peace to further consolidate power in their realm, and in 1744 Nguyen Phuc Khoat (r. 1738–1765) proclaimed himself king. Yet a sociopolitical crisis was triggered with the ascension to the throne of a minor, Nguyen Phuc Thuan (r. 1765–1777), as power actually resided

➤ NGUYEN BINH KHIEM

Nguyen Hoang's decision not to contest the Trinh Lords and instead carve out a fiefdom of his own in the south appears to have been suggested to him by the famous scholar-official and soothsayer Nguyen Binh Khiem (1491–1585). The son of a mandarin, he topped the official government examination in 1535 but resigned his position seven years later in protest against widespread corruption in the Mac dynasty's bureaucracy and court. From the base of his White Cloud Hermitage in Hai Duong, Nguyen Binh Khiem became an educator, poet, and much sought after adviser with purported prophetic skills. Thus, apart from Nguyen Hoang, he is also alleged to have advised the ambitious Trinh Kiem to become the power behind the throne of the restored Le dynasty rather than to claim it himself.

If true, Nguyen Binh Khiem's advice arguably changed the course of early modern Vietnamese history. By masterminding new political configurations and dynamics, the highly volatile atmosphere of sixteenth-century Vietnamese elite politics was defused, and at least intermittently, regicide and further fratricidal were prevented. Instead, the Le nominally preserved imperial hegemony, whereas the ambitions of the more dynamic Trinh and Nguyen families were directed onto two separate but occasionally colliding paths: actual exercise of Trinh power in the north, Dang Ngoai, and the building of an independent Nguyen domain, Dang Trong, through southward expansion. This essentially bipolar order would last for two centuries, only to quickly disintegrate when challenged by the Tay Són Rebellion.

—Tobias Rettig

with his dominant regent. By then, if not earlier, military complacency seems to have set in; moreover, the central regions of the Nguyen kingdom were largely uncovered because the dynasty's military forces were concentrated at the northern border to the Trinh domain, while their militia forces were based in the Gia Dinh area (which contains present-day Ho Chi Minh City). These circumstances provided fertile ground for three brothers from Tay Son village to start a local uprising. They claimed to restore power to Nguyen Phuc Thuan, but the Tay Son Rebellion soon embroiled the eastern part of the Indochinese peninsula into a three-pronged 30-year contest over political supremacy between the Nguyen, the Tay Son, and the Trinh/Le, which included foreign interference.

In 1777 the Tay Son pushed the Nguyen southward into the marshy Mekong Delta and wiped out almost the entire Nguyen family. In 1785 the Tay Son inflicted a severe defeat on Prince Nguyen Anh (1762–1820), the only survivor. Although Nguyen Anh, who initially had sought refuge in Bangkok and in the Gulf of Siam, eventually managed to establish a fairly secure operational base in Gia Dinh in late 1788, his overall prospects still looked extremely bleak.

Hence, the most capable of the Tay Son, Nguyen Hue (1753–1792), who had declared himself emperor in 1788, unified Dang Ngoai and Dang Trong in 1789 by driving out the Chinese forces called in by the last Le emperor for protection. Yet Nguyen Hue's premature death in 1792 left in place as emperor a ten-year old boy incapable of holding the newly created realm together. Within ten years, well-planned seasonal campaigns and arguably also the military support organized by French bishop Pigneau de Béhaine (1741–1799) allowed Nguyen Anh to take Thang Long on July 20, 1802, and to establish Vietnam's last dynasty.

From the Prince to the Sun King—The Absolutist State in Early Modern Europe

The concept of absolutism in the early modern era developed from a secular theory of authoritative statecraft into the rule of an individual invested with both divine authority and unchecked power. Political theories of state, monarchy, and constitutionalism varied between regions. Most importantly, the rise of absolutist theory denoted the rise of centralized government in western Europe and the perpetuation of the *ancien régime*.

In Italy, Niccoló Machiavelli and his political theories were fostered by the attitudes of the Renaissance. His work *The Prince* (written in 1513 and published in 1532) stated that princes could maintain control of their realm by establishing authority over the people and by not deviating from the accepted and functional political institution. His theories were used by rulers such as Catherine de Medici to justify violence and to defend their self-interested governance. Others, such as the Huguenot Innocent Gentillet and Frederick the Great, widely condemned
